CASE NO. GR-93-172

2.3

DIRECT TESTIMONY

OF

JAMES A. GRAY

MISSOURI PUBLIC SERVICE,

A DIVISION OF UTILICORP UNITED, INC.

CASE NO. GR-93-172

- O. Please state your name and business address.
- A. My name is James A. Gray and my business address is Missouri Public Service Commission, P. O. Box 360, Jefferson City, Missouri.
 - Q. Please state your educational background.
- A. I received a Bachelor of Science degree in Psychology as well as one in General Studies from Louisiana State University, and I received a Master of Science degree in Special Education from the University of Tennessee.

 Additionally, I completed several postgraduate courses in research and statistics at the University of Missouri Columbia.
- Q. Please state your professional experience as it relates to your duties with the Missouri Public Service Commission (Commission).
- A. From 1978 to 1980 I was a Research Analyst with the Missouri Department of Mental Health where I conducted statistical analyses. I have been a Statistician with the Commission for approximately twelve years. I have

filed testimony before this Commission on weather
normalization of sales for electric, water and natural gas.

Q. What is the purpose of your direct testimony?

A. I will address the weather normalization of
gas sales for the residential-firm and commercial-firm rate
classes of the Northern and Southern Systems for the test

WEATHER NORMALIZATION METHOD

Q. What are the objectives of weather normalization methods?

year ending September 30, 1992.

- A. The objectives of weather normalization methods are: (1) to estimate the relationship between weather-sensitive usage and appropriate measures of weather; and (2) to make the appropriate sales adjustment for the differences between normal and actual weather conditions.
- Q. What is the major factor which determines the weather sensitivity of gas usage?
- A. The major weather-sensitive use of gas is space heating. The winter heating season starts in November and runs through to March.
- Q. What weather variable was used in your analysis?
- A. I used a standard measure called "heating degree days" (HDD) as a weather variable.

Q. How did you calculate heating degree days?

A. Heating degree days are calculated as the

difference between 65 degrees and the mean daily temperature (the average of the high and low daily temperature), when the mean daily temperature is below 65°F. On days warmer than a mean daily temperature of 65°F, the heating degree days are equal to zero. For example, if a day had a mean daily temperature of twenty degrees (20°F), then that day would have 45 heating degree days (65 - 20 = 45). But if a day had a mean daily temperature of eighty degrees (80°F), the heating degree days would be zero.

Q. Why is it important to set rates based on usage levels that are representative of normal weather conditions?

A. Test year revenues from current rates are calculated by multiplying rate components by the corresponding levels of usage. If the usage levels are below normal, then test year revenues will also be below normal. Since fixed costs do not vary with weather, an abnormally low level of revenues compared to costs would result in the Company getting a larger rate increase (Costs - Revenues) than would be just and reasonable. On a going-forward basis, proposed volumetric rates are calculated by dividing allowed test-year costs by test-year gas usage for each class. Thus, if usage levels reflect the influence of

1 2

abnormal weather, these proposed rates will be distorted by these deviations from normal weather conditions.

3 4

0. What is the Staff's recommendation for weather-adjusted gas usage for the residential-firm and

5

commercial-firm customer classes? 6

26

The Staff recommends a 6.2 percent increase from actual test year usage for the residential-firm rate classes and a 5.9 percent increase over actual test year usage for the commercial-firm rate class. The Staff's weather adjustment reflects the warmer than normal winter weather in the test year. This increase does not reflect the Staff's customer growth annualization.

- Q. What information did you give to Staff Accountant Larry Cox for his customer growth annualization?
- Schedule 1, attached to this testimony, shows normalized Ccfs per customer for each billing month during the test year by rate class and system. Staff witness Dr. Michael Proctor adjusted the commercial-firm usage for transfers to other rate classes during the test year.
- How did you match gas usage data and weather data in your methodology?
- The Company's customer billing records had historical information on meter reading dates and billed The historical data cover the usage for each bill cycle. billing months of October, 1991 through September, 1992. The daily HDD's from the Staff's weather data files were

25

matched to each of the bill reading cycles for each of the test year's twelve billing months. Thus, gas usage data was matched directly with the weather over the days in which the gas was used.

- How did you calculate average billing month weather from the data sets?
- For each bill cycle, gas usage was divided by the corresponding number of days to calculate average daily usage. The same procedure was applied to the weather Then both were averaged for each billing month variables. using the percent of customers in each bill cycle as the weights.
- How did you measure the relationship between Q. gas usage and weather conditions?
- Statistical regression (a mathematical Α. procedure to explain how one variable correlates with another) was used to estimate the relationship for each of the classes in each of the Company's seven districts. The regressions were run on usage per customer per day against HDD per day.
- How closely did your regression results match 0. actual usage per customer for the billing months in the test year?
- My Schedules 2-1 through 2-4, attached to this testimony, show that the regression line closely fits

At

customers in each bill cycle. These are then added over

the billing month to get the total adjustment for a district. Then the normalized usage for the districts are aggregated into the Northern and Southern Systems.

- How did you calculate peak demand for each Q. class?
- The regression results were used with the Α. average number of winter customers and the average of the thirty year weather series of annual coldest days of 65 heating degree days to calculate the peak demand. demands were provided to Staff witness Anne Ross.
- Q. What is the source of the usage data you used in your analysis?
- Monthly gas consumption and number of customers for each billing cycle and each customer class

and district were provided by the Company for October of 1 1991 to September, 1992. 2 3 Where did you get the weather data for your Q. 4 analysis? 5 Mean daily temperatures were obtained from 6 Α. the National Oceanic and Atmospheric Administration's 7 (NOAA) weather stations at Kansas City International 8 Airport, Windsor, Nevada, Sedalia, Clinton, Lexington, 9 Marshall, Salisbury, Brookfield, and Spickard, Missouri. 10 What historical period did you use for normal 11 Q. degree days? 12 Average monthly temperature values were 13 Α. computed over the thirty-year period from July 1, 1961 to 14 June 30, 1991. 15 Does this conclude your direct testimony?

Yes, it does. A.
