REBUTTAL TESTIMONY OF RUSSELL A. FEINGOLD

CASE NO. GR-2006-0422

NOVEMBER 21, 2006

1 **Q. PLEASE STATE YOUR NAME AND BUSINESS ADDRESS.**

2 A. My name is Russell A. Feingold and my business address is Four PPG Place, Pittsburgh,
3 Pennsylvania 15222.

4

5 **Q. BY WHOM ARE YOU EMPLOYED AND IN WHAT CAPACITY?**

6 A. I am a Managing Director of Navigant Consulting, Inc. ("NCI") and co-leader of the
7 Litigation, Regulatory & Markets Group within the firm's Energy Practice.

8

9 **Q. HAVE YOU PREVIOUSLY SUBMITTED DIRECT TESTIMONY BEFORE THE**
10 **MISSOURI PUBLIC SERVICE COMMISSION ("COMMISSION") IN THIS**
11 **PROCEEDING?**

12 A. Yes. I previously submitted direct testimony in this proceeding on behalf of Missouri
13 Gas Energy ("MGE" or the "Company") concerning its: (1) proposed weather normal for
14 purposes of adjusting its base rates for the effect of weather; (2) revenue adjustments to
15 weather normalize its gas volumes and to annualize its current level of customers; (3)
16 class revenue allocation; and (4) various rate design proposals.

17

1 **Q. WHAT IS THE PURPOSE OF YOUR REBUTTAL TESTIMONY IN THIS**
2 **PROCEEDING?**

3 A. The purpose of my rebuttal testimony is to respond to the position of the Missouri Public
4 Service Commission Staff (the "Staff") on the appropriate weather normal for MGE, its
5 related adjustment to the Company's test year revenues, and its proposed rate design for
6 the Company's Small General Service ("SGS") rate class, and to the position of the
7 Office of Public Counsel ("OPC") on the appropriate rate design for the Company's
8 customers. I will specifically respond to the direct testimonies of Staff witnesses Curt
9 Wells, James A. Gray, Paul R. Harrison, and Anne E. Ross, and OPC witness Barbara A.
10 Meisenheimer. I will also briefly comment on the Staff's rate design proposals for the
11 Company's Residential Service, Large General Service ("LGS"), and Large Volume
12 Service ("LVS") classes sponsored by Staff witness Ross.

13
14 **Q. CAN YOU BRIEFLY SUMMARIZE YOUR FINDINGS AND**
15 **RECOMMENDATIONS RELATED TO THESE PARTIES' PRESENTATIONS?**

16 A. Yes. Based on my review of the points and underlying support presented by witnesses
17 Wells, Gray, Harrison, Ross, and Meisenheimer concerning the Company's proposed
18 weather normal, related revenue adjustment, and its rate design proposals, I have reached
19 the following findings and recommendations:

20 • Staff's continued use of a 30-year Heating Degree Day ("HDD") average to
21 normalize the Company's annual gas volumes for rate case purposes ignores the

inability of this measure to derive a realistic and achievable level of normal sales upon which MGE's base rates are premised. This deficiency will perpetuate the Company's continued inability to recover the Commission's approved level of margin revenues. As a result, I recommend that this Commission reject Staff's proposed measure of normal weather and adopt the Company's proposal to use a 10-year HDD average to normalize its annual gas volumes for rate case purposes.

- This Commission should reject Staff's proposed weather normalization adjustment to revenue of \$5,226,629, (*i.e.*, an increase over the actual revenue level experienced in the test year), derived by Staff witness Paul R. Harrison, since it greatly overstates the Company's base revenues under normal weather conditions because Staff's proposed measure of normal weather is deficient. In my expert opinion, Staff has overstated the Company's base revenues by approximately \$2.9 million – which means the Company must achieve an unrealistically high level of base revenues in future years to have a reasonable opportunity to earn its allowed rate of return (to be determined in this rate proceeding). As a result, I recommend that the Commission reject Staff's adjustment to revenues and adopt the Company's proposed weather normalization adjustment to revenue of \$2,342,430.

- The Commission should reject Staff's proposal to increase each rate component for the SGS class by the percentage increase in class revenues because it ignores the margin losses contributed by this class caused primarily by declining use per

1 customer and variations in weather from normal levels. I recommend the
2 Commission adopt the Company's rate design proposal for the SGS class because
3 it remedies the continuing margin losses experienced in this class.

4 • This Commission should reject OPC's proposal that there be no change to the
5 current level of the monthly customer charge for the Company's residential
6 customers. This proposal is seriously deficient for a number of important
7 reasons:

- 8 ✓ It is not reflective of the true costs of serving the Company's residential
9 customers;
- 10 ✓ It will perpetuate the intra-class cross subsidies that exist within the
11 residential class – which means that some customers will continue to
12 overpay for gas delivery service while others will continue to underpay;
- 13 ✓ It will cause more customers to overpay by a greater amount for gas
14 service during colder than normal periods because the Company's
15 volumetrically derived commodity charges will be disproportionately
16 increased under OPC's rate design proposal;
- 17 ✓ It ignores the ratemaking initiative embodied in the Missouri
18 Legislature granting the Commission (by the enactment of SB 179) the
19 authority to approve for gas utilities ratemaking mechanisms that
20 address the problem of margin revenue losses; and

1 ✓ It will not provide an appropriate ratemaking foundation for the
2 Company to offer energy efficiency and conservation programs for the
3 benefit of its customers because of the disincentive the Company has to
4 promote such programs caused by revenues and sales that are directly
5 linked through the OPC's increased emphasis placed on a volume-
6 based rate structure in its rate design proposal.

7
8 As a result, I recommend that the Commission adopt the Company's Straight Fixed-
9 Variable ("SFV") rate structure proposal for the residential class, which is conceptually
10 identical to Staff's rate design proposal for this class, as presented and discussed in the
11 direct testimony of Staff witness Ross.

12
13 **Q. BEFORE CONTINUING, PLEASE DESCRIBE THE ISSUES YOU ARE**
14 **RESPONSIBLE FOR THAT HAVE BEEN SETTLED BY THE PARTIES IN**
15 **THIS PROCEEDING.**

16 A. There are two issues I covered in my direct testimony that have been settled by the
17 parties: (1) the allocation of the Company's revenue increase to its rate classes; and (2)
18 the Company's customer annualization adjustment to revenues. With regard to the
19 settlement on class revenues, it is my understanding that the parties have agreed that any
20 revenue increased authorized by the Commission will be spread among the rate classes
21 on the basis of an equal percentage of margin revenues. For example, a four (4) percent

1 increase in the Company total margin revenue will be applied to the margin revenues for
2 each individual class on the same percentage basis.

3 No further transfer of revenue responsibility between the rate classes will be proposed,
4 under that agreement. Finally, while the Company does not accept the cost of service
5 studies presented by the Staff or the OPC (as discussed by Company witness Mr. Amen),
6 the Company agrees, for purposes of settlement, with the equal percentage revenue
7 spread as a fair disposition of this issue for purposes of this case.

8
9 **1. WEATHER NORMAL AND RELATED REVENUE ADJUSTMENT**

10
11 **Q. PLEASE SUMMARIZE THE COMPANY'S PROPOSAL TO NORMALIZE ITS**
12 **ANNUAL CUSTOMER LOADS FOR WEATHER.**

13 A. The Company is proposing to use a 10-year Heating Degree-Days ("HDD") average to
14 normalize its annual gas volumes for rate case purposes. Historically, a 30-year HDD
15 average computed by the National Oceanographic and Atmospheric Administration's
16 ("NOAA") has been used to normalize its gas volumes for weather. Under the 10-year
17 average, the Company's measure of normal weather will be established at 4,967 HDD for
18 its Kansas City and St. Joseph service areas, and at 4,450 HDD for its Joplin service area.
19 Currently, 5,249 HDD for the Kansas City and St. Joseph areas, and 4,602 HDD for the
20 Joplin area are the measures of normal weather embedded in MGE's present distribution
21 rates. These values are NOAA's most recently computed 30-year averages for the years

1 1971-2000 (NOAA calculates its 30-year average once every ten years).

2

3 **Q. WHY HAS THE COMPANY CHOSEN TO MODIFY THE MANNER IN WHICH**
4 **ITS GAS VOLUMES ARE WEATHER NORMALIZED?**

5 A. The use of a 10-year HDD average will result in improved forecasting for normalizing
6 MGE's gas volumes. This means that the annual gas volumes established in the
7 Company's current rate case would better reflect the expected normal weather conditions
8 during the period in which its base rates will be in effect.

9

10 **Q. HOW DOES THE CHOICE OF WEATHER NORMAL AFFECT THE**
11 **COMPANY'S NORMAL SALES LEVEL FOR ITS RESIDENTIAL CLASS IN**
12 **THIS PROCEEDING?**

13 A. Under the Company's proposal to utilize a 10-year HDD average, the annual normalized
14 use per customer for its residential class is 834 Ccf. Under Staff's proposal to utilize a
15 30-year HDD average, the use per customer level increases by just over 4 percent to 868
16 Ccf.

17

18 **Q. CAN A HIGHER USE PER CUSTOMER LEVEL HAVE A NEGATIVE IMPACT**
19 **ON THE COMPANY'S ABILITY TO RECOVER ITS APPROVED MARGIN**
20 **REVENUES?**

1 A. Yes. As exhibited in Schedule RAF-9, the Company experienced margin losses in its
2 residential service rate class in each of the last seven years due to fluctuations in gas
3 volumes caused primarily by declining use per customer and variations in weather from
4 normal levels. In my opinion, the Commission's adoption of a 30-year weather normal
5 for that period contributed to the Company's revenue shortfall because the "baseline" use
6 per customer used to design rates was too high – as Schedule RAF-7 readily
7 demonstrates. As a result, the Company's ability to fully recover its approved margin
8 revenues could not be achieved simply because it never was able to achieve the assumed
9 higher level of gas sales that the Commission assumed to be "normal" – even when
10 weather was colder than normal such as in 2001.

11

12 **Q. PLEASE SUMMARIZE STAFF WITNESS WELLS' POSITION ON THE**
13 **APPROPRIATE WEATHER NORMAL FOR THE COMPANY.**

14 A. Staff witness Wells uses the 30-year time period used by NOAA and the World
15 Meteorological Organization ("WMO") – which consists of the three most recent
16 consecutive decades from January 1, 1971 through December 31, 2000. Mr. Wells states
17 in his direct testimony that his choice of this 30-year period is based on: (1) previous
18 Staff analysis; (2) Commission decisions; and (3) the standards for normal weather
19 variables established by NOAA and the WMO.

20

1 **Q. WHAT TYPE OF SUPPORT DOES STAFF WITNESS WELLS PROVIDE FOR**
2 **HIS CHOICE OF A 30-YEAR WEATHER NORMAL?**

3 A. Most of the support for Staff witness Wells' position on an appropriate weather normal
4 for MGE was elicited from him in his responses to Company data requests on the subject.
5 I have included his responses in Schedule RAF-16. His responses specifically address
6 the three bases for his choice of the 30-year weather normal, and certain definitional
7 considerations and conceptual beliefs that underlie his preference for this choice of
8 method.

9
10 Based on my review of his responses, I was able to ascertain why he believes a weather
11 normal based on 30 years of HDD data is preferable to other measures of normal
12 weather. For clarity purposes, I have summarized Mr. Wells' support for a 30-year
13 weather normal as follows: (1) 30-year weather normals are standards of NOAA and
14 WMO and are officially generated numbers; (2) the Commission has utilized 30-year
15 normals as its practice or policy; and (3) the Staff has conducted "analysis" in support of
16 a 30-year normal.

17
18 From a definitional and conceptual perspective, Mr. Wells believes that the "test year"
19 concept as practiced in Missouri amounts to a "back cast" of a utility's normal operating
20 conditions to compute its revenue requirement and rates rather than a "forecast" of
21 conditions expected to occur during the time when new rates are in effect. As such, he

1 believes that the choice of the weather normal should not be based upon its ability to
2 represent, or predict, future weather.

3

4 **Q. DO YOU AGREE WITH MR. WELLS' POINTS IN SUPPORT OF THE**
5 **CONTINUED USE OF THE 30-YEAR AVERAGE FOR PURPOSES OF**
6 **WEATHER NORMALIZATION?**

7 A. No. For each of the points made by Mr. Wells, I will explain why his thinking is flawed,
8 misplaced, or irrelevant and should be given little weight by the Commission in selecting
9 the most appropriate basis upon which the Company should derive its weather
10 normalized gas volumes.

11

12 **Q. PLEASE EXPLAIN THE RELEVANCE OF MR. WELLS' POINT THAT 30-**
13 **YEAR NORMALS ARE STANDARDS AND OFFICIALLY GENERATED**
14 **NUMBERS.**

15 A. His point has no relevance whatsoever in selecting the most appropriate basis for the
16 Company's weather normal. While it is true that NOAA generates a 30-year HDD
17 average, and uses it as a standard (together with the WMO) for "normal weather," it is
18 also true that the NOAA attaches no significance to this average other than it is an
19 historic average. In fact, on its website, NOAA provides some very informative
20 commentary on the topic of "*what is a climate normal?*"

21 *"The term climatic "normal" had faced a dilemma since its introduction a*
22 *century and a half ago. As noted by Guttman (1989), "Climatologists generally*

1 *understand that a normal is simply an average of a climatic element over thirty*
2 *years...a normal value is usually not the most frequent value not the value above*
3 *which half the cases fall.” The casual user, however, tends to (erroneously)*
4 *perceive the normal as what they should expect. Dr. Helmut E. Landsburg, who*
5 *became Director of Climatology of the U.S. Weather Bureau in 1954 and, later,*
6 *Director of Environmental Data Service, summarized the dilemma quite well*
7 *over four decades ago (Landsburg, 1955). “The layman is often misled by the*
8 *word. In his every-day language the word normal means something ordinary or*
9 *frequent...When (the meteorologist) talks about “normal,” it has nothing to do*
10 *with a common event...For the meteorologist the “normal” is simply a point of*
11 *departure or index which is convenient for keeping track of weather*
12 *statistics...We never expect to experience “normal” weather.”¹*
13

14 This referenced section of the NOAA website goes on to discuss the appropriateness of
15 using its “normals” for predictive purposes - “Normals are best used as a base against
16 which climate during the following decade can be measured.” I interpret this to mean
17 that the NOAA weather normals should not be used to represent current or future weather
18 conditions as would be required in a utility’s test year. Based on these explanations, it is
19 clear that the standard for normal weather used by NOAA and the WMO has no
20 meaningful significance within the context of a test year used for utility ratemaking
21 purposes. Moreover, the fact that 30-year normals calculated by NOAA might make
22 them “official” measures confers no special value on them.

23
24 **Q. DO YOU AGREE WITH MR. WELLS THAT THE COMMISSION HAS**
25 **UTILIZED 30-YEAR NORMALS AS ITS PRACTICE OR POLICY?**

¹ <http://www.ncdc.noaa.gov/oa/climate/normals/usnormals.html>

1 A. Yes, I do. However, this point does not dispose of the threshold question of which
2 measure of normal weather is the most appropriate basis for weather normalizing MGE's
3 gas volumes. In my opinion, the use of the 30-year average by the Commission is
4 effectively a policy without foundation.

5
6 **Q. HAVE YOU REVIEWED THE STAFF 'ANALYSIS' REFERRED TO BY MR.**
7 **WELLS IN SUPPORT OF HIS 30-YEAR WEATHER NORMAL?**

8 A. Yes. The Staff "analysis" consists of the following two pieces of rate case testimony:
9 1. Testimony on behalf of Staff by then Missouri Climatologist Dr. Wayne Decker in
10 Case No. GR-92-165 (Laclede Gas Company)
11 2. Testimony on behalf of Staff by then Missouri State Climatologist Dr. Steve Qi Hu in
12 Case No. GR-99-315 (Laclede Gas Company)

13
14 **Q. PLEASE DESCRIBE THE TYPE AND EXTENT OF THE ISSUES RAISED IN**
15 **THIS STAFF TESTIMONY.**

16 A. In the "Decker" testimony, he addresses his preference for a 30-year weather normal over
17 the weather normal proposed by Laclede Gas Company which used the entire weather
18 history records (from the 1890s according to the testimony) for St. Louis. Interestingly,
19 in my opinion, the reasons given by Dr. Decker in support of his preference for a 30-year
20 weather normal also are supportive of the use of a 10-year weather normal as proposed
21 by the Company. In the "Qi Hu" testimony, all but one question and answer addresses

1 weather issues other than the basis for establishing a utility's weather normal. In Dr. Qi
2 Hu's words, the purpose of his testimony, "...will explain the necessity for adjusting the
3 station temperatures and a procedure I used in correcting the Saint Louis Lambert
4 International Airport station temperature time series for the period 1961-1998."

5
6 **Q. DOES THIS PRIOR TESTIMONY PROVIDE ANY MEANINGFUL**
7 **"ANALYSIS" TO SUPPORT THE USE OF A 30-YEAR WEATHER NORMAL**
8 **OVER THE COMPANY'S PROPOSAL TO USE A 10-YEAR WEATHER**
9 **NORMAL?**

10 A. No, it does not. More importantly, in this proceeding, the Staff has made no attempt to
11 analyze the reasonableness of its proposed 30-year weather normal within the specific
12 context of MGE's service areas. This is in contrast to the detailed weather analysis
13 presented by the Company in support of its proposed 10-year weather normal, as
14 presented in my direct testimony and supporting schedules.

15
16 **Q. PLEASE EXPLAIN HOW THE CHOICE OF A WEATHER NORMAL FOR THE**
17 **COMPANY RELATES TO THE CONCEPT OF A TEST YEAR AND MR.**
18 **WELLS' UNDERSTANDING OF THIS CONCEPT.**

19 A. In his response to a Company data request, Mr. Wells stated his belief that "Missouri is a
20 test year state." On that basis alone, he apparently disagrees with the notion that the
21 choice of a weather normal for MGE should best reflect the weather expected to occur

1 when its rates in this case go into effect. Very simply, Mr. Wells seems to reject the
2 forward-looking nature of establishing a utility's rates, and the importance of deriving the
3 utility's revenue requirement and associated rates for its recovery, using a test year that is
4 reflective of costs and sales levels that will be experienced. This concept is a
5 fundamental tenet of utility ratemaking and has been acknowledged by other experts in
6 the field.² In fact, this Commission has taken a similar view of the test year concept
7 when it stated in a prior proceeding that, "the purpose of using a test year is to create or
8 construct a reasonably expected level of earnings, expenses and investment during the
9 future period during which the rates to be determined herein will be in effect."³

10
11 **Q. ASIDE FROM ITS ABILITY TO REASONABLY REPRESENT NORMAL**
12 **WEATHER DURING THE TIME A UTILITY'S RATES ARE IN EFFECT,**
13 **WHAT OTHER ATTRIBUTE SHOULD AN APPROPRIATELY ESTABLISHED**
14 **WEATHER NORMAL POSSESS?**

15 A. It is my judgment that the utility's weather normal should create a situation where the
16 utility will have an equal opportunity to gain or lose from the method. Under the

² For example, see *The Regulation of Public Utilities* by Charles F. Phillips, Jr. At page 182, "A Commission is setting rates for the future, but it has only past experience (expenses, revenues, demand conditions) to use as a guide. Philosophically, the strict test year assumes the past relationship among revenues, costs, and net investment will continue into the future."

³ See the Report and Order of the Missouri Public Service Commission in Case Nos. TR-77-214 and TR-79-213, *Re Southwestern Bell Telephone Company*, 23 Mo.P.S.C. (N.S.) 374, 377 (1980).

1 Commission's current method for selecting a utility's weather normal - which is based
2 upon the 30-year HDD average - the situation has been created for the Company where it
3 is much more likely to lose than to gain. This imbalance is evident upon review of the
4 Company's margin losses experienced in its residential class as contained in Schedule
5 RAF-9 presented with my direct testimony.
6

7 **Q. ARE THERE OTHER GAS UTILITIES IN NORTH AMERICA THAT USE A 10-**
8 **YEAR AVERAGE FOR THEIR WEATHER NORMALIZATION PROCESS?**

9 A. Yes. Gas utilities in North America that employ a 10-year average for purposes of
10 weather normalizing their gas volumes include: Questar Gas Company, Southwest Gas
11 Corporation, Nicor Gas Company, Southern Union Gas Company (various local Texas
12 jurisdictions), New England Gas Company (recently acquired by National Grid), Citizens
13 Utilities Company (Arizona jurisdiction), Vermont Gas Systems, and Terasen Gas
14 (formerly BC Gas Utility Limited now part of Kinder Morgan).
15

16 **Q. PLEASE SUMMARIZE THE REASONS WHY THE COMMISSION SHOULD**
17 **ADOPT THE COMPANY'S PROPOSAL FOR A 10-YEAR WEATHER**
18 **NORMAL FOR MGE.**

19 A. The Commission should adopt the Company's 10-year HDD average for the following
20 important reasons:
21

- 1 1. As discussed in my direct testimony, the Company's 10-year HDD average more
2 accurately reflects the changing trends of the weather, which is exactly what is sought
3 when using this average, for ratemaking purposes, as a measure of normal weather in
4 the Company's service areas;
- 5 2. The 10-year weather normal provides a more balanced opportunity for the Company
6 to win or lose compared to the asymmetry demonstrated historically under Staff's 30-
7 year weather normal;
- 8 3. The 10-year weather normal more closely tracks the ongoing variation in HDD
9 compared to the 30-year weather normal (see pages 3 and 4 of Schedule RAF-3);
- 10 4. The 10-year weather normal is a partial solution to the continuing margin losses
11 experienced by the Company caused by warmer than normal weather (as defined
12 under a 30-year weather normal), and the resulting lower use per customer and lower
13 base revenues than those approved by the Commission;
- 14 5. The Company's proposed 10-year weather normal uses the most recent weather data
15 available to establish the basis for the Company's normal sales volumes, while the
16 Staff's 30-year weather normal relies upon weather data that already is five (5) years
17 old, and can be as much as ten (10) years old depending on the timing of a particular
18 utility's rate case filing;
- 19 6. In more recent times, the 10-year weather normal has been adopted by other state
20 utility commissions and implemented by the gas utilities under their jurisdiction; and

7. The Commission can take comfort in the fact that, as I previously demonstrated in my direct testimony, the odds of returning back to the colder climatic conditions represented by the current NOAA 30-year average are very low.

2. RATE DESIGN

A. Small General Service

Q. PLEASE EXPLAIN WHY YOU RECOMMEND THAT THE COMMISSION REJECT STAFF'S RATE DESIGN PROPOSAL FOR THE COMPANY'S SGS CLASS.

A. Staff's rate design proposal sponsored by Staff witness Ross does not address the continuing margin losses in this class caused by declining use per customer and variations in weather from normal levels. Under Staff's proposal, the current monthly customer charge and commodity charges would be increased by the same percentage that the class revenues are proposed to be increased. This approach is in lieu of proposing a SFV rate design as Staff had done for the Company's residential rate class. According to Staff witness Ross, she is concerned about determining a "fair Delivery Charge for all customers currently taking service on that tariff" because of the diversity in size and usage patterns among SGS customers.

While I agree with Staff's comments concerning diversity in the SGS class, and the use of a SFV rate design, I do not believe that justifies ignoring the fixed cost nature of gas

1 delivery service provided by MGE and the need to implement a ratemaking solution that
2 addresses the Company's continuing margin losses. Specifically, the Company has
3 proposed to increase the monthly Customer Charge to \$31.00, which is supported by its
4 cost of service study results, and to decrease the present Commodity Charges to levels
5 necessary to recover the balance of the proposed revenue increase assigned to this class
6 not recovered through the Customer Charge. While both the Company and Staff have
7 embraced the recovery of MGE's fixed costs through the fixed components of rates, as
8 evidenced by their conceptual agreement on the use of a SFV rate design for the
9 residential class, Staff does not appear to be as receptive to comparable treatment of the
10 recovery of fixed costs through fixed charges in the SGS class. Yet, with almost \$35
11 million in fixed costs valued at the Company's proposed rate of return, the SGS class
12 represents an important part of the Company's ability to recover its fixed cost of service.
13 As such, it is critical that the traditional rate structure for the SGS class, or a suitable
14 alternative, properly reflects the recovery of these fixed costs in the fixed portion of the
15 rate structure. Staff's proposed rate design does not accomplish this important objective
16 while the Company's rate design proposal does.

17
18 If the Commission is unwilling to implement MGE's rate design proposal for the SGS
19 class, MGE would suggest – as an alternative to the Staff's proposed SGS rate design
20 which will perpetuate, and even exacerbate, MGE's chronic problem of under-recovering
21 fixed costs by way of volumetric rate elements – placing the entirety of the SGS rate

1 increase on the fixed rate element (i.e., the customer charge) and leaving the existing
2 volumetric rate elements for the SGS class as is.
3

4 **B. Residential Service**

5 **Q. PLEASE ELABORATE ON THE DEFICIENCIES IN OPC WITNESS**
6 **MEISENHEIMER'S PROPOSAL TO RETAIN THE "STATUS QUO" WITH**
7 **REGARD TO THE COMPANY'S CURRENT RESIDENTIAL CUSTOMER**
8 **CHARGE STARTING WITH YOUR POINT THAT THE OPC'S PROPOSAL IS**
9 **NOT REFLECTIVE OF THE TRUE COSTS OF SERVING THE COMPANY'S**
10 **RESIDENTIAL CUSTOMERS.**

11 **A.** Since Ms. Meisenheimer relies on a flawed cost of service study as the basis for her
12 customer charge recommendation, OPC's rate design proposal does not reflect the true
13 cost of serving the residential customer class. The specific reasons why OPC's cost of
14 service study is flawed are presented in the rebuttal testimony of Company witness
15 Ronald J. Amen. In contrast to the OPC's rate design proposal, the Company's
16 proposed SFV rate structure for its residential class achieves a fundamental objective of
17 ratemaking--the proper alignment of costs with revenues and rates - which the OPC's
18 proposal fails to achieve. In fact, it is my opinion that the OPC's proposal is regressive
19 in nature in that it moves the Company's rates further away from the true cost of
20 providing gas delivery service.
21

1 As described in my Direct Testimony, under the SFV rate structure, residential customers
2 will simply pay a flat monthly fee for the delivery services provided by MGE, and will
3 continue to pay on a volumetric basis through the Purchased Gas Adjustment ("PGA")
4 for the actual amount of gas commodity used each month. The SFV rate structure
5 properly reflects the true fixed cost nature of the gas distribution business, allowing MGE
6 a reasonable opportunity to recover its fixed costs of providing gas delivery service,
7 while its customers will pay for that service in an appropriate and equitable manner.
8 Finally, the pricing of the Company's gas delivery services in this manner properly
9 portrays to its customers: (1) the fixed nature of the underlying costs; (2) the delivery-
10 only characteristics of the service; and (3) the fact that natural gas is the real commodity
11 being purchased via the Company's gas delivery system.

12
13 **Q. PLEASE EXPLAIN WHY THE OPC'S RATE DESIGN PROPOSAL WILL**
14 **PERPETUATE THE INTRA-CLASS CROSS SUBSIDIES THAT EXIST WITHIN**
15 **THE COMPANY'S RESIDENTIAL CLASS.**

16 **A.** The higher Basic Service Charge proposed by the Company is fairer to customers in the
17 residential class than the OPC's proposal and will cure the chronic cross-subsidy that
18 exists between small and large residential customers caused by the mismatch between
19 their costs of service and base rate revenues. Under the OPC proposal, customers who
20 have very little annual usage per month can pay less than half of their allocated delivery
21 service costs, while very high use customers pay well over 100%. This is because the

1 monthly customer charge of \$11.65 is substantially less than the allocated cost of service
2 to residential customers of fixed delivery service costs, so low use customers tend to
3 underpay for these costs. OPC's largely volumetric residential rate design will
4 perpetuate, and likely exacerbate, the intra-class cross subsidies that exist within the
5 residential class – some customers will continue to overpay for gas delivery service while
6 others will continue to underpay.

7
8 Under the Company's SFV proposal, each residential customer, regardless of gas
9 consumption, pays the full share of allocated fixed delivery service costs, leaving none of
10 these costs to be collected through a volumetric charge. Accordingly, a gas customer will
11 not "overpay" or "underpay" his or her share of the delivery service costs based on the
12 customer's consumption relative to the average consumption for the class.

13
14 Since the Company's fixed delivery service cost is actually \$27.50 per month for a
15 residential customer, a monthly customer charge of any amount less than \$27.50 per
16 month means customers will pay either more or less than their 'fair' amount, depending
17 upon the individual customer's annual usage relative to the class average. The more the
18 charge deviates from the cost-based \$27.50 amount, the more unfair the rate design
19 becomes to its customers. Compared with the Company's proposal, the OPC proposal
20 will result in greater over and underpayment by individual residential customers based on
21 their relative usage - and in greater bill instability on a monthly and seasonal basis.

1

2 **Q. BUT SHOULDN'T THE COMPANY'S RESIDENTIAL CUSTOMERS "PAY**
3 **MORE AS THEY USE MORE" NATURAL GAS, AND DOESN'T THE**
4 **COMPANY'S SFV RATE DESIGN PROPOSAL PRECLUDE THAT FROM**
5 **HAPPENING?**

6 A. No. The explanation to fully understand this misperceived sense of customer equity is
7 tied to what they are using more of – either gas delivery service or the gas commodity
8 itself. If a customer increases its use of gas delivery service from the Company, it is
9 entirely equitable to charge residential customers the same fixed rate for gas delivery
10 service because, as I discussed previously, the costs incurred to provide this delivery
11 service do not vary with volume taken by the customer.

12

13 For the gas commodity itself, the Company's residential customers will continue to pay
14 more for this service as they use more under a SFV rate design - just as they do currently
15 under MGE's Purchased Gas Cost Adjustment ("PGA") mechanism – because the
16 Company incurs additional gas commodity costs as its customers demand more gas. The
17 SFV rate design proposal will not change the application of the PGA to customers'
18 monthly gas bills. There is a close alignment of costs with rates, thus, making it
19 equitable to charge customers more as they use more gas commodity supplied by the
20 Company.

21

1 **Q. PLEASE EXPLAIN WHY THE OPC'S RATE DESIGN PROPOSAL WILL**
2 **CAUSE MORE RESIDENTIAL CUSTOMERS TO OVERPAY BY A GREATER**
3 **AMOUNT FOR GAS SERVICE DURING COLDER THAN NIRMAL PERIODS.**

4 A. The OPC's largely volumetric rate design proposal will cause more residential customers
5 to overpay by a greater amount for gas service during colder than normal periods because
6 the Commodity Charge for that rate class will be disproportionately increased.

7

8 While the Company's proposed SFV rate design will increase the average customer's
9 bills in the summer and shoulder months, when customer bills are at their lowest levels, it
10 will decrease or moderate the increase in customer's bills in the winter months, when
11 bills are at their highest levels. The customer bill analysis described in my Direct
12 Testimony shows that under the Company's proposed SFV rate design, approximately
13 72% of MGE's customers will experience a bill decrease in the month of January,
14 typically the coldest month of the year, with the remaining customers experiencing a bill
15 increase (See Schedule RAF-11). Moreover, under colder than normal weather, these
16 same customers will experience greater decreases in their bills, and there will be a greater
17 number of customers who would also experience decreases in their bills under the
18 proposed SFV rate design.

19

20 **Q. PLEASE EXPLAIN WHY THE OPC'S RATE DESIGN PROPOSAL WILL NOT**
21 **PROVIDE AN APPROPRIATE RATEMAKING FOUNDATION FOR THE**

1 **COMPANY TO OFFER ENERGY EFFICIENCY AND CONSERVATION**
2 **PROGRAMS FOR ITS CUSTOMERS.**

3 A. The OPC's rate design proposal will not provide an appropriate ratemaking foundation
4 for the Company to offer energy efficiency and conservation programs for the benefit of
5 its customers because of the disincentive the Company has to promote such programs
6 caused by revenues and sales that are directly linked through the OPC's increased
7 emphasis placed on a volume-based rate structure in its rate design proposal. OPC's rate
8 design proposal requires that most of the residential revenue requirement for fixed costs
9 be recovered through volumetric rates, so that MGE can fully recover these costs only if
10 its customers consume a certain level of gas. Basing MGE's rates upon a set level of gas
11 volumes creates a significant financial disincentive for it to aggressively promote energy
12 efficiency for its customers. When MGE's customers use less gas, the Company's
13 financial performance suffers because recovery of fixed costs is reduced in proportion to
14 the reduction in gas sales.

15
16 As I indicated in my Direct Testimony, the declines in gas use per customer have been
17 substantial for MGE over the last ten years (see Schedule RAF-7). The annual average
18 use per customer has declined significantly in MGE's residential and general service
19 classes. Over the last seven years, MGE incurred margin losses in each of those years
20 due to fluctuations in gas volumes caused primarily by declining use per customer and
21 variations in weather from normal levels (See Schedule RAF-9). The total margin losses

1 during that period amounted to almost \$42 million, or approximately \$6 million per year.
2 Under its proposed SFV rate design, the Company will be able to promote energy
3 efficiency and conservation programs for its customers without the continual real threat
4 of margin losses due to declining gas sales per customer. It is therefore entirely
5 reasonable for the Company to condition its willingness to undertake the natural gas
6 conservation initiatives described in MGE witness Hendershot's rebuttal testimony on
7 the Commission's adoption of the SFV rate design proposed by MGE and endorsed by
8 the Staff.

9
10 **Q. IS THERE A FUNDAMENTAL PRESUMPTION UNDERLYING THE**
11 **POSITION OF OPC WITNESS MEISENHEIMER WITH REGARD TO HER**
12 **PROPOSAL TO LEAVE THE RESIDENTIAL CUSTOMER CHARGE AT ITS**
13 **CURRENT LEVEL?**

14 **A.** Yes. A fundamental presumption of OPC's residential rate design proposal is that a
15 volumetrically weighted rate design provides the most appropriate prices signals to
16 customers related to gas consumption. In reality, however, such a rate design conveys
17 inaccurate and improper price signals to customers, because it recovers fixed costs
18 through the volumetric components of the utility's rate structure. As described earlier in
19 my rebuttal testimony, this undesirable situation can: (1) increase revenue variability for
20 the Company, (2) contribute to the instability of customer bills, and (3) needlessly inflate
21 bills in the winter months, when customers face the greatest pressure on their household

1 budgets from utility bills. The Company's SFV rate design proposal minimizes these
2 undesirable effects and aligns the price signals to customers with the underlying costs of
3 providing delivery service.

4
5 **Q. CAN THE PARTICULAR RATE DESIGN ULTIMATELY APPROVED FOR**
6 **THE COMPANY MAKE THE CHOICE OF A WEATHER NORMAL A MORE**
7 **IMPORTANT CONSIDERATION TO MGE?**

8 A. Yes. If the Commission decides not to adopt the SFV rate design concept proposed by
9 the Company and the Staff, and/or to the extent the monthly customer charges of MGE's
10 other rate classes are not increased to the cost-based levels proposed by MGE, it makes
11 the choice of a weather normal a much more important consideration to the Company in
12 being afforded a reasonable opportunity to recover its fixed costs of providing gas
13 delivery service to its customers. This is because the level of the Company's
14 volumetrically-derived Commodity Charges has a strong impact on: (1) the Company's
15 ability to recover through rates its approved revenue requirement; and (2) the variability
16 of those revenues caused by changes in the weather and its customers' gas usage.

17
18 Under the OPC's rate design proposal, the level of the Company's current Commodity
19 Charge in its residential class will increase, with the anticipated increase in its revenue
20 requirement, subjecting a greater portion of MGE's revenue requirement to the vagaries
21 of weather. Such a rate design will undoubtedly further deteriorate the Company's

1 financial situation in warmer than normal weather – which is exactly the outcome the
2 Company is seeking to remedy in this proceeding. As more of the Company’s revenue
3 requirement is designed to be recovered through its Commodity Charges, it places more
4 importance on getting the sales volume level right – which is directly impacted by the
5 choice of weather normal.
6

7 **Q. PLEASE SUMMARIZE THE REASONS WHY THIS COMMISSION SHOULD**
8 **REJECT THE OPC’S RATE DESIGN PROPOSAL.**

9 A. The Commission should reject the OPC’s rate design proposal for the following reasons:

- 10 ✓ It is not cost-based;
- 11 ✓ It will perpetuate, and likely exacerbate, existing cross-subsidies among
12 residential customers;
- 13 ✓ It will cause more residential customers to overpay by a greater amount in
14 the winter;
- 15 ✓ It ignores the critical problem of the Company’s margin revenue losses;
16 and
- 17 ✓ It is not supportive of energy efficiency and conservation initiatives.

18
19 **Q. DO YOU HAVE COMMENTS ON THE STAFF’S RATE DESIGN PROPOSAL**
20 **FOR THE COMPANY’S RESIDENTIAL CLASS?**

1 A. Yes. As I discussed earlier, I believe the Company and Staff are in conceptual
2 agreement on the rate design that is most appropriate for MGE's residential customers --
3 a SFV rate structure. As a point of clarification, the Company does not accept the
4 Staff's cost of service study, which is largely based on Staff's capacity utilization method
5 of allocating the demand portion of distribution mains advocated by Staff witness Beck
6 (as discussed by Company witness Amen in his rebuttal testimony). However, both the
7 Staff and Company supported rate design proposals provide for the recovery of the entire
8 amount of the residential non-gas revenue requirement in a single fixed monthly charge
9 (i.e., the Staff's "Delivery Charge" and the Company's "Basic Service Charge").

10

11 Differences between the originally filed total revenue increase and class revenue
12 allocation proposals by Staff and the Company, with the class revenue allocations based
13 on their respective cost of service studies, led to the differing levels of fixed charge rates
14 for the residential class (i.e., Staff's Delivery Charge of \$23.48 per month versus the
15 Company's Basic Service Charge of \$27.50 per month). With the agreement between
16 the parties regarding the allocation of class revenue responsibility, the foregoing
17 differences should be resolved when final rates are submitted to the Commission for
18 approval.

19

20 C. Large General Service and Large Volume Service

1 **Q. DO YOU HAVE ANY COMMENTS REGARDING THE STAFF'S PROPOSED**
2 **RATE DESIGN FOR THE LGS AND LVS CLASSES?**

3 **A.** Although MGE does not oppose the rate design the Staff has proposed through its direct
4 testimony for the LGS and LVS classes, other proposals for these rate classes may be
5 made by other parties in rebuttal testimony. If so, the Company reserves the ability to
6 comment on those proposals in surrebuttal testimony.

7

8 **Q. MR. FEINGOLD, DOES THIS COMPLETE YOUR REBUTTAL TESTIMONY?**

9 **A.** Yes, it does.

Data Request

Data Request No.	0207
Company Name	MO PSC Staff-(All)
Case/Tracking No.	GR-2006-0422
Date Requested	10/17/2006
Issue	Revenue - Weather Normalization
Requested From	Curt Wells
Requested By	Michael R Noack
Brief Description	NA
Description	Referring to Page 4, lines 11-13 of Mr. Wells' direct testimony, please provide a copy of the reference source containing the statement on climate normals made by the National Oceanographic and Atmospheric Administration ("NOAA").
Due Date	11/6/2006

Response:

Reference source can be found at web site http://cdo.ncdc.noaa.gov/climate_normals/clim81/MOnorm.pdf. Specific reference is at page 3, under Computational Procedures, first sentence. (copy attached)

CLIMATOGRAPHY OF THE UNITED STATES NO. 81

Monthly Normals of Temperature, Precipitation, and Heating and Cooling Degree Days

1971-2000

MISSOURI

Page 3

NOTES

Product Description:

This Climatology includes 1971-2000 normals of monthly and annual maximum, minimum, and mean temperature (degrees F), monthly and annual total precipitation (inches), and heating and cooling degree days (base 65 degrees F). Normals stations include both National Weather Service Cooperative Network and Principal Observation (First-Order) locations in the 50 states, Puerto Rico, the Virgin Islands, and Pacific Islands.

Abbreviations:

No. = Station Number in State Map
 COOP ID = Cooperative Network ID (1:2=State ID, 3:6=Station Index)
 WBAN ID = Weather Bureau Army Navy ID, if assigned
 Elements = Input Elements (X=Maximum Temperature, N=Minimum Temperature, P=Precipitation)
 Call = 3-Letter Station Call Sign, if assigned
 MAX = Normal Maximum Temperature (degrees Fahrenheit)
 MEAN = Average of MAX and MIN (degrees Fahrenheit)
 MIN = Normal Minimum Temperature (degrees Fahrenheit)
 HDD = Total Heating Degree Days (base 65 degrees Fahrenheit)
 CDD = Total Cooling Degree Days (base 65 degrees Fahrenheit)

Latitude = Latitude in degrees, minutes, and hemisphere (N=North, S=South)
 Longitude = Longitude in degrees, minutes, and hemisphere (W=West, E=East)
 Elev = Elevation in feet above mean sea level
 Flag 1 = * if a published Local Climatological Data station
 Flag 2 = + if WMO Fully Qualified (see Note below)

HIGHEST MEAN/YEAR = Maximum Mean Monthly Value/Year, 1971-2000
 MEDIAN = Median Mean Monthly Value/Year, 1971-2000
 LOWEST MEAN/YEAR = Minimum Mean Monthly Value/Year, 1971-2000
 MAX OBS TIME ADJUSTMENT = Add to MAX to Get Midnight Obs. Schedule
 MIN OBS TIME ADJUSTMENT = Add to MIN to Get Midnight Obs. Schedule

Note: In 1989, the World Meteorological Organization (WMO) prescribed standards of data completeness for the 1961-1990 WMO Standard Normals. For full qualification, no more than three consecutive year-month values can be missing for a given month or no more than five overall values can be missing for a given month (out of 30 values). Stations meeting these standards are indicated with a '+' sign in Flag 2. Otherwise, stations are included in the normals if they have at least 10 year-month values for each month and have been active since January 1999 or were a previous normals station.

Map Legend: Numbers correspond to 'No.' in Station Inventory; Shaded Circles indicate Temperature and Precipitation Stations, Triangles (Point Up) indicate Precipitation-Only Stations, Triangles (Point Down) indicate Temperature-Only Stations, and Hexagons indicate stations with Flag 1 = *.

Computational Procedures:

A climate normal is defined, by convention, as the arithmetic mean of a climatological element computed over three consecutive decades (WMO, 1989). Ideally, the data record for such a 30-year period should be free of any inconsistencies in observational practices (e.g., changes in station location, instrumentation, time of observation, etc.) and be serially complete (i.e., no missing values). When present, inconsistencies can lead to a non-climatic bias in one period of a station's record relative to another, yielding an "inhomogeneous" data record. Adjustments and estimations can make a climate record "homogeneous" and serially complete, and allow a climate normal to be calculated simply as the average of the 30 monthly values.

The methodology employed to generate the 1971-2000 normals is not the same as in previous normals, as it addresses inhomogeneity and missing data value problems using several steps. The technique developed by Karl *et al.* (1986) is used to adjust monthly maximum and minimum temperature observations of continuous U.S. stations to a consistent midnight-to-midnight schedule. All monthly temperature averages and precipitation totals are cross-checked against archived daily observations to ensure internal consistency. Each monthly observation is evaluated using a modified quality control procedure (Peterson *et al.*, 1996), where station observation departures are computed, compared with neighboring stations, and then flagged and estimated where large differences with neighboring values exist. Missing or discarded temperature and precipitation observations are replaced using a weighting function derived from the observed relationship between a candidate's monthly observations and those of up to 20 neighboring stations whose observations are most strongly correlated with the candidate site. For temperature estimates, neighboring stations were selected from the U.S. Historical Climatology Network (USHCN; Karl *et al.* 1990). For precipitation estimates, all available stations were potential neighbors, maximizing station density for estimating the more spatially variable precipitation values.

Peterson and Easterling (1994) and Easterling and Peterson (1995) outline the method for adjusting temperature inhomogeneities. This technique involves comparing the record of the candidate station with a reference series generated from neighboring data. The reference series is reconstructed using a weighted average of first difference observations (the difference from one year to the next) for neighboring stations with the highest correlation with the candidate. The underlying assumption behind this methodology is that temperatures over a region have similar tendencies in variation. If this assumption is violated, the potential discontinuity is evaluated for statistical significance. Where significant discontinuities are detected, the difference in average annual temperatures before and after the inhomogeneity is applied to adjust the mean of the earlier block with the mean of the latter block of data. Such an evaluation requires a minimum of five years between discontinuities. Consequently, if multiple changes occur within five years or if a change occurs very near the end of the normals period (e.g., after 1995), the discontinuity may not be detectable using this methodology.

The monthly normals for maximum and minimum temperature and precipitation are computed simply by averaging the appropriate 30 values from the 1971-2000 record. The monthly average temperature normals are computed by averaging the corresponding monthly maximum and minimum normals. The annual temperature normals are calculated by taking the average of the 12 monthly normals. The annual precipitation and degree day normals are the sum of the 12 monthly normals. Trace precipitation totals are shown as zero. Precipitation totals include rain and the liquid equivalent of frozen and freezing precipitation (e.g., snow, sleet, freezing rain, and hail). For many NWS locations, indicated with an '*' next to 'HDD' and 'CDD' in the degree day table, degree day normals are computed directly from daily values for the 1971-2000 period. For all other stations, estimated degree day totals are based on a modification of the rational conversion formula developed by Thom (1966), using daily spline-fit means and standard deviations of average temperature as inputs.

Brief Description	NA

Description	At page 4, lines 20-23 of his direct testimony, Mr. Wells states that "International agreements have established that three-decade periods are appropriately long and uniform time frames for the calculation of normals." Please provide copies of all such "international agreements" that reach this conclusion.
--------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Due Date	11/6/2006
-----------------	-----------

Response:

International agreements referred to are agreements among the 185 member states and territories of the World Meteorological Organization to, among other purposes, "promote standardization of meteorological and related observations and ensure uniform publication of observations and statistics."(www.wmo.ch/web-en/wmo_purposes.html)

To further that purpose, members accepted the convention of the three consecutive decade definition of normal, the current period running from 1971-2000. (See response to DR 207)

This convention was promulgated by the World Meteorological Organization in 1989 as "Calculation of monthly and Annual 30-year Standard Normals, WCDP-No.10, WMO-TD/341", Geneva. Page two, Section III., STANDARD NORMALS AND PROVISIONAL NORMALS, states: "The Technical Regulations define normals as 'period averages computed for a uniform and relatively long period comprising at least three consecutive ten-year periods...'" (attached)

CALCULATION OF MONTHLY AND ANNUAL 30-YEAR STANDARD NORMALS

Prepared by a meeting of experts, Washington, D.C., USA,

March 1989

WCDP-No. 10

WMO-TD/No. 341

WORLD METEOROLOGICAL ORGANIZATION

The World Climate Programme launched by the World Meteorological Organization (WMO) includes four components:

- The World Climate Data Programme
- The World Climate Applications Programme
- The World Climate Impact Studies Programme
- The World Climate Research Programme

The World Climate Research Programme is jointly sponsored by the WMO and the International Council of Scientific Unions.

This report has been produced without editorial revision by the WMO Secretariat. It is not an official WMO publication and its distribution in this form does not imply endorsement by the Organization of the ideas expressed.

CALCULATION OF MONTHLY AND ANNUAL 30-YEAR STANDARD NORMALS

I. PURPOSE

The purpose of this document is to establish general procedures to be used for the calculation of the WMO monthly and annual 30 year (1961-1990 and following periods) standard and provisional normals and to suggest other climatic descriptors. These procedures were produced for use by all countries, and will be produced and distributed as a computer application and written document. However, all countries may use this information but certain procedures may be difficult to implement without the use of computers.

II. BACKGROUND

The International Meteorological Committee in 1872 decided to compile mean values over a uniform period in order to assure comparability between data collected at various stations. The outgrowth of this was the recommendation for calculation of 30 year normals for stations. As stated in WMO Technical Regulation No. 49, Vol. 1, Section B "Each Member should establish and periodically revise normals for stations whose climatological data are distributed on the Global Telecommunications System in accordance with the provisions of Annex II (Manual on Codes, Volume 1) and forward these normals to the Secretariat". The initial period was determined to be 1901-1930. Succeeding periods were decided to be at 30-year intervals (i.e. 1931-1960, 1961-1990). However, many WMO members have been updating their 30-year normals at the completion of each decade. This was recommended in 1956 and noted in Technical Note No. 84. The WMO regulations require the calculations only each 30-year period. The WMO guidelines and regulations provide little guidance on "how to" calculate the 30-year normals; "how to" handle missing data; "how to" handle periods of data that contain obviously erroneous data; or "how much" data is required for a 30-year normal verses provisional normals. This paper is intended to provide a procedure with generalized rules and data completeness or quality indicators to be used in the calculation of the 30-year normals and to provide suggested ancillary data descriptors that will help to better describe the climate in statistical terms. These procedures are presented as practical advice only and are not considered to be the "best or only" methods of calculating normals.

III. STANDARD NORMALS AND PROVISIONAL NORMALS

Climate data are often more useful when they are compared with standard or normal values. The Technical Regulations define normals as "period averages computed for a uniform and relatively long period comprising at least three consecutive ten-year periods" and climatological standard normals as "averages of climatological data computed for consecutive periods of 30 years as follows: 1 January 1901 to 31 December 1930, 1 January 1931 to 31 December 1960, etc." In the case of stations for which the most recent climatological standard normal is not available (either because the station has not been in operation for the period of 30 years or for some other reason), provisional normals should be calculated. Provisional normals are

short-period means based on observations extending over a period of at least ten years. The concept of "normals calculation" is extended in this document to include an analysis of data homogeneity and the calculation of other climate descriptors. This extension is based on WMO Tech Note 84.

IV. DATA EXAMINATION

It is assumed that routine hourly, daily and monthly quality control has been performed on the data as suggested in the WMO/TD-No. 111, WCP-85, Guidelines on the Quality Control of Surface Climatological Data. Climatological quality control (i.e. homogeneity) investigation and data inspection over a long period should also be performed. The following paragraphs recommend steps to analyze data homogeneity and identify heterogeneities (ref. WMO Guide to Climatological Practices). Suggested procedures to examine data homogeneity are:

1. Examine the data for trends, shifts (step functions), spurious data values, other data problems and evidence of data heterogeneity. Techniques include:
 - a. Basic data descriptions e.g. frequency counts, means, medians, standard deviations, variances, extremes, and percentiles.
 - b. Graphical analysis e.g. histograms, time series displays and areal comparisons.
 - c. Nonparametric tests e.g. runs, sign, trend and serial correlation. The significance level should be .95.
2. Examine the data for heterogeneities by analyzing the results of the techniques listed above for identifying the cause of non-climatic discontinuities and variations. Potential non-climatic heterogeneities are:
 - a. Station/sensor relocation e.g. horizontal and/or vertical movement of some or all of the station sensors to a new location.
 - b. Instrument effects e.g. drift, calibration, maintenance and new/replacement instruments.
 - c. Environmental effects e.g. vegetation changes, building effects on airflow and land use changes.
 - d. Systematic observer bias and observing/coding changes.

After the data have been examined, it is necessary to decide if heterogeneity exists and if the cause is climatic or non-climatic. Reasons for the decision should be documented. Data should be classified as:

- i Essentially homogeneous;
- ii Essentially heterogeneous because of:
 - station/sensor relocation
 - instrument effects
 - observing and coding practices
 - local environmental effects.
- iii Data not examined.

Adjustments may be made, if heterogeneities are known to be caused by documented non-climatic effects. Spurious data values may be eliminated/corrected. There are three options:

- a. Adjust data to make a homogeneous record, e.g. to latest location or proper sensor calibration, if the form and magnitude of the correction is known. Sometimes adjustments can be made for station/sensor relocations, instrument effects and observing/coding practices. Adjustments for environmental effects should not be made (e.g. urban warming).
- b. Split the long-term heterogeneous series into one or more separate, homogeneous parts and treat the individual parts separately.
- c. Process data as if it were homogeneous, but identify the data as heterogeneous. If changes have been made to the data then at the completion of the above process the data should be re-examined. If desired, interstation comparisons may be made.

Suggested procedures include:

- a. Determine statistical distributions and characteristics of the data.
- b. Use statistical characteristics to determine the applicability and validity of models such as:
 - i Double mass analysis
 - ii Multiple regression
 - iii Spatial analysis
 - iv Time series analysis
 - v Principal component analysis.
- c. Apply valid models.
- d. If the comparisons indicate potential heterogeneities, the data should be further investigated.

CALCULATION PROCEDURES FOR SURFACE ELEMENTS

CALCULATION OF MONTHLY VALUES (DAILY TO MONTHLY)

Table 1 identifies the principal climatological elements and units of measure for which monthly values should be calculated.

TABLE 1. PRINCIPAL CLIMATOLOGICAL SURFACE ELEMENTS

	UNIT	PRECISION
1. Precipitation Total	mm	.1
2. Days with Precipitation Greater than or Equal to 1 mm	count	1
3. Temperature Tx, Tn, Tm	deg C	.1
4. Pressure	kPa	.01
5. Sunshine	hours	.1
6. Vapour pressure	kPa	.01

NOTE: Precision recommendations are based on consistency of calculations, even though it is meteorologically unreasonable to imply the indicated precision for annual totals.

The method of calculation is described below. When arithmetic means are to be calculated for each month of each year from daily data the following rule (hereafter referred to as the "3/5 rule") applies. If more than 3 consecutive daily values are missing or more than 5 daily values in total in a given month are missing, the monthly mean should not be computed and the year-month mean should be considered as missing. The number of days for which monthly means are calculated is N, where N can vary from 23 to 31. The symbol S in the equations indicates a summation of all N values.

- a. Precipitation Total--Totals shall be calculated for each month of each year from daily data. Monthly totals should be based on a full month's data. However, accumulated amounts during the month are acceptable in lieu of individual daily totals provided that each accumulation is for 3 or less days. If accumulated data are used, the monthly total should be identified with an "accumulation" indicator. If any daily totals are missing and the corresponding accumulated totals are also missing, the monthly total should not be computed and the year-month total should be considered as missing.
- b. Days With Precipitation Greater Than or Equal to 1mm--Totals should be calculated for each month of each year from daily data. Monthly totals should be based on a full month's data, that is, no missing daily counts are permitted.
- c. Temperature--Calculate average monthly maximum (\bar{T}_x), minimum (\bar{T}_n), and mean (\bar{T}_m) temperature from the daily values Tx, Tn, Tm as follows:

$$\bar{T}_x = \frac{ST_x}{N} ; \quad \bar{T}_N = \frac{ST_N}{N}$$

$$T_M = \frac{S([T_x + T_N]/2)}{N}$$

Note that because of rounding errors, \bar{T}_M should not be calculated by averaging the monthly means of maximum (T_x) and minimum (T_n) temperatures, but rather by summary and averaging the daily values (T_x, T_n). The "3/5 rule" for missing data applies.

- d. Pressure--Calculate average monthly sea level pressure (\bar{P}_{sl}) and station level pressure (\bar{P}_{st}) from the average daily pressures observed at 00,06,12,18Z.

$$\bar{P}_{sl} = \frac{S((P_{sl,00} + P_{sl,06} + P_{sl,12} + P_{sl,18})/4)}{N}$$

$$\bar{P}_{st} = \frac{S((P_{st,00} + P_{st,06} + P_{st,12} + P_{st,18})/4)}{N}$$

- e. Sunshine--Totals should be calculated for each month of each year from daily data. Monthly totals should be based on a full month's data, that is, no missing daily totals are permitted.

- f. Vapour Pressure--Average daily vapour pressure (VP) should be computed by averaging 24 hourly observations per day. If 24 hourly values are not available for each day, the daily average may be alternatively calculated from 8 (00,03,06,09,12,15,18,21Z) observations per day. The number of observations per day should be identified with a 'frequency' indicator. The monthly mean vapour pressure (VP) should be calculated as follows and the "3/5 rule" for missing data applies.

$$\bar{VP} = \frac{SVP}{N}$$

Other climatological elements for which monthly values may be calculated are listed in Table 2.

TABLE 2. OTHER SUGGESTED CLIMATOLOGICAL ELEMENTS (LISTED IN PRIORITY ORDER) AND METHOD OF CALCULATION

ELEMENT	METHOD	UNIT	PRECISION
Relative Humidity (max, min)	i	%	1
Dewpoint (mean)	vii	deg C	.1

ELEMENT	METHOD	UNIT	PRECISION
Wind direction (prevailing)	ii	deg	10
Wind speed (mean)	vii	m/s	.1
Vector wind direction (mean)	vii	deg	1
Vector wind magnitude (mean)	vii	m/s	.1
Wind steadiness (mean)	vii	---	---
Snowfall (total)	iv	cm	.1
Soil temperature (mean per observation time at depth)	iii	deg C	.1
Days with specified phenomenon (e.g. thunder, hail, fog, gale, blowing sand)	ii	count	1
Cloud amount (total)	vii	okta	.1
Pan evaporation	vii	mm	.1
Solar radiation	vi	MJ/m ²	.01

METHOD NOTES

(i) Determine daily maximum and minimum relative humidity RH_x and RH_N from 24 hourly observations per day. If 24 hourly values are not available each day, then 8 (00,03,06,12,15,18,21Z) observations each day should be used. The number of observations each day should be identified with a frequency indicator. The average monthly values \overline{RH}_x and \overline{RH}_N are calculated as follows and the "3/5 rule" for missing data applies.

$$\overline{RH}_x = \frac{SRH_x}{N}$$

$$\overline{RH}_N = \frac{SRH_N}{N}$$

(ii) Prevailing wind direction should be calculated by identifying the most frequent direction that occurred within a month. Frequency counts should be based on 24 hourly observations per day. If 24 hourly observations are not available for each day, then 8 (00,03,06,09,12,15,18,21Z) observations each day should be used. The number of observations per day will be identified with a "frequency" indicator. The number of direction categories (36 is preferred) should be identified by a "direction" indicator.

(iii) See methodology described in Section V.1.c for maximum temperature.

(iv) See methodology described in Section V.1.a. for precipitation total.

(v) See methodology described in Section V.1.b for days with precipitation greater than or equal to 1mm.

(vi) See methodology described in Section V.1.e for sunshine.

(vii) See methodology described in Section V.1.f for vapour pressure.

2. NORMALS CALCULATIONS (Year-Month to Monthly Normal to Annual Normal)

Monthly 30-year standard normals are calculated from year-month values. If for a given month (e.g. January) 3 consecutive year-month values (e.g. January 1970, 1971, 1972) are missing or more than 5 values in total for the given month are missing, the 30-year standard normal should not be calculated.

Monthly Normals Z for an element X are calculated by

$$Z = \frac{\overline{SX}}{M}$$

where M is the number of months for which year-month values are available (M can vary between 25 and 30).

Annual normals for an element are calculated by averaging the 12 monthly normals. For precipitation totals, sunshine, solar radiation, days with specified phenomenon, standard annual normals should be calculated by adding all 12 monthly normals. Normals should exist for all 12 months to calculate an annual normal, that is, no missing monthly normals are permitted if an annual normal is to be calculated.

3. PROVISIONAL NORMALS (Heterogeneous Data and/or Short-Period)

If a data series has not been examined for homogeneity or other data problems, or if a data series has at least 10 year-month values but fewer than that required for the calculation of 30-year standard normals, then provisional normals Z' for an element $\overline{X'}$ may be calculated by:

$$Z' = \frac{\overline{SX'}}{M'}$$

where M' is the number of months for which year-month values are available (M' can vary between 10 and as much as 30 for heterogeneous data). The years for which monthly values are available are identified by a "year" indicator.

Provisional annual normals are computed by averaging 12 provisional monthly normals. For precipitation totals, sunshine, solar radiation, days with specified phenomenon, provisional annual normals should be calculated by adding all 12 provisional monthly normals. Provisional monthly normals should exist for all 12 months to calculate a provisional annual normal, that is, no missing provisional monthly normals are permitted if a provisional annual normal is to be calculated.

All provisional monthly or annual normals should be identified by a "provisional" indicator.

VI. NORMALS FOR UPPER AIR ELEMENTS

Monthly averages should be calculated for the elements listed in Table 3 at the following levels:

1. Surface
2. 85 kPa
3. 70 kPa
4. 50 kPa
5. 30 kPa
6. 20 kPa
7. 15 kPa
8. 10 kPa
9. 05 kPa
10. 03 kPa

TABLE 3. PRINCIPAL CLIMATOLOGICAL UPPER AIR ELEMENTS

	UNIT	PRECISION
1. Height	gpm	1
2. Temperature	deg C	.1
3. Dewpoint depression/RH	deg C%	.1/1
4. Wind direction	deg	1
5. Wind speed	m/s	1
6. Wind steadiness	---	---

Averages should be calculated for each element at each level for the separate hours of 00,06,12,18Z by:

$$\bar{Y} = \frac{\sum SX}{N}$$

where \bar{Y} is the monthly average for element X at a given level for a given time, and N is the number of daily values for which the average is calculated. (N can vary between 1 and 31)

Decadal means should be calculated by:

$$Z_1 = \frac{\sum \bar{Y}_1}{M_1} \quad Z_2 = \frac{\sum \bar{Y}_2}{M_2} \quad Z_3 = \frac{\sum \bar{Y}_3}{M_3}$$

where Z_1, Z_2, Z_3 are the decadal monthly means for the periods 1961-70, 71-80, 81-90; $\bar{Y}_1, \bar{Y}_2, \bar{Y}_3$ are the year-month averages at a given level, observation time and month for the periods 1961-70, 71-80, 81-90; and M_1, M_2, M_3 are the number of year-month values in the decades 1961-70, 71-80, 81-90 for which means are calculated (M_1, M_2, M_3 can vary between 1 and 10). The decadal means Z_1, Z_2, Z_3 and counts M_1, M_2, M_3 should be considered an integral part of the upper air normals.

The monthly normal Z should be calculated by:

$$Z = \frac{S\bar{Y}}{M} \quad (\text{note } \bar{Y} \text{ is the monthly average, i.e. year-month value})$$

where

$$M = M_1 + M_2 + M_3$$

Note that the monthly normals Z should be calculated from the year-month value Y and not from the decadal means.

The annual normal is calculated by averaging the 12 monthly normals. Normals should exist for all 12 months to calculate an annual normal. All upper-air normals will be considered provisional unless data homogeneity can be demonstrated.

VII. OTHER CLIMATE DESCRIPTORS

Descriptors other than normals should be provided to allow more complete assessment of the variable nature of climate.

Because of CLIMAT reporting requirements (ref. WMO 306) it is necessary to calculate precipitation quintiles as described in WMO Guide to Climatological Practices, Chapter 8, 1983, pp. 8.5-8.7. Quintiles are required for monthly precipitation totals. A "method" indicator should accompany the calculated quintiles.

Other descriptors that should be considered for individual decades and the whole 1961-90 period are:

1. Standard deviation of daily and monthly maximum, minimum and mean temperatures, and sea level and station level pressure and upper air parameters.
2. Percentiles at the 10, 25, 50, 75, 90 levels for all elements calculated for both daily and monthly data.
3. Frequency of non-occurrence of precipitation, sunshine and cloud amount.
4. Distribution of extremes.

VIII. SUPPLEMENTAL INFORMATION

To ensure proper use and understanding of the Normals (provisional or standard), the following information should accompany the normals:

1. Country code
2. Country name
3. Station name

4. WMO region
5. Latitude (deg, min, N or S)
6. Longitude (deg, min, E or W)
7. Elevation
8. WMO Block/Index Number
9. Quality and processing indicators
 - a. Accumulation (number of accumulation periods)
 - b. Frequency (either 24 or 8 observations per day)
 - c. Years (individual years with data)
 - d. Direction (either 36, 16 or 8 point compass)
 - e. Method for computing quintiles
 - i. From data
 - ii. From gamma distribution model
 - iii. From other model
 - f. Provisional normal
 - i. Yes or no (no indicates standard normal)
 - g. Reasons for provisional normal
 - i. Insufficient period of record
 - ii. Heterogeneity
 1. Station/sensor relocation
 2. Instrument effects
 3. Observing/coding practices
 4. Local environmental effects
 5. Unknown
 - iii. Both VIII.9.g.i and VIII.9.g.ii
 - h. Data completeness
 - i. Standard normal with no monthly values missing
 - ii. Standard normal with some monthly values missing
 - iii. Number of data values used to compute a provisional normal.

This document is the result of an expert meeting held in Washington, D.C., USA, in March 1989. Its intent is to provide general information to Members as they prepare to calculate its standard and/or provisional 30 year Normals. The expert participants in the meeting were:

- K. Davidson, WMO
- N. Guttman, National Climatic Data Center, USA
- C. Ropelewski, Climate Analysis Center, USA
- N. Canfield, Climate Analysis Center, USA
- E. Spackman, Meteorological Office, UK
- D. Gullett, Atmospheric Environment Service, Canada

Missouri Public Service Commission

Data Request

Data Request No.	0209
Company Name	MO PSC Staff-(All)
Case/Tracking No.	GR-2006-0422
Date Requested	10/17/2006
Issue	Revenue - Weather Normalization
Requested From	Curt Wells
Requested By	Michael R Noack
Brief Description	NA

Description	At pages 4-5 of Mr. Wells' direct testimony, he states that Staff's choice of the 30-year period derived by NOAA for normalizing MGE's annual loads for weather is based on "previous Staff analysis, Commission decisions, and these standards for normal weather variables established by NOAA and the WMO." Please provide all documents and any other explanatory information to support the basis for Mr. Wells' statement as it relates to: a. Previous Staff analysis b. Commission decisions c. Standards for normal weather variables established by NOAA and WMO.
--------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Due Date	11/6/2006
-----------------	-----------

Response:

a. Previous Staff analysis;

1. Testimony on behalf of Staff by then Missouri State Climatologist Dr. Wayne Decker in Case No. GR-92-165 (attached)

2. Testimony on behalf of Staff by then Missouri State Climatologist Dr. Steve Qi Hu in Case No. GR-99-315 (attached)

b. Commission Decisions:

Commission Report and Order relied upon is Commission Report and Order (January 22, 1997) in MGE Case No. GR-96-285.

(Relevant sections attached: Cover page, List of Appearances, Table of Contents, Weather Normalization Adjustment section. Pages 1-4, 16-18.)

c. Standards for normal weather variables established by NOAA and WMO:

This convention was promulgated by the World Meteorological Organization in 1989 as "Calculation of monthly and Annual 30-year Standard Normals, WCDP-No.10, WMO-TD/341", Geneva. (See response to DR 208)

Exhibit No. 3
Date 8/13/92 Case No. GR-92-165
Reporter GM

DIRECT TESTIMONY

OF

WAYNE L. DECKER

LACLEDE GAS COMPANY

CASE NO. GR-92-165

Q. What is your name and address?

A. I am Wayne L. Decker. I live at 1007 Hulen Drive, Columbia, Missouri 65203.

Q. What is your professional position?

A. I serve the University of Missouri-Columbia as a Professor of Atmospheric Science. I have also been designated as the State Climatologist for Missouri.

Q. How long have you been employed by the University of Missouri?

A. I came to the University of Missouri an Assistant Professor in September 1949. I was designated as the State Climatologist when the National Weather Service phased-out their program of service to the States in the late 1960's.

Q. Where were you employed prior to your appointment at the University of Missouri?

A. I worked as a climatologist for the National Weather Service (called at that time the U. S. Weather Bureau) and served in World War II as a meteorologist with the U. S. Navy in the Pacific theater.

Q. What has been your formal education?

A. My undergraduate education was at Central College in Pella, Iowa with a major in Chemistry. I received post-graduate training in Meteorology at UCLA in 1943-44. I hold MS and Ph.D degrees from Iowa State University in Climatology.

Q. Do you have any other professional qualifications?

A. Yes. To save time, I have attached a copy of relevant biographical information as Schedule 1.

Direct Testimony of
Wayne L. Docker

1 Q. What does the field of climatology cover?

2 A. Climatology is the study of the variations in
3 climate, both spatial and temporal, and documentation of the effects
4 of these variations on man. Climatology involves the use of
5 statistical procedures for determining the risks of climatic events
6 from a probability point of view. The climatologist must assess the
7 effects of discontinuities in the climatic records due to natural
8 causes, changes in observational procedures, and effects of man on the
9 environment. The climatologist interprets the historical observational
10 series in terms of the effects of climate on human food supply and
11 health, weather sensitive operations and economic growth and
12 development.

13 Q. Does climatology provide information of value to the
14 assessment of heating demands?

15 A. Yes. For many years the utility companies,
16 consumers, and the State Commissions regulating the supply of fuel and
17 power have used climatic records as a basis for setting rates and
18 anticipating energy needs. The climatologist can provide valuable
19 assistance with the interpretation of the historical climatic records.

20 Q. Does it make a difference where the weather
21 observations are taken for describing the climatic characteristics of
22 a city or region?

23 A. Yes, when one interprets climate data over an
24 extended period it is very important to review the history of the
25 weather station locations and the type of instrumentation used.
26 Attached to this testimony as Schedule 2 is a summary prepared by the
27 National Oceanic and Atmospheric Administration (NOAA) of the downtown
28 and Lambert Field locations where weather observations have been taken
29 and the instrumentation used in St. Louis.

Direct Testimony of
Wayne L. Decker

1 Q. Is it a standard practice for climatologists to refer
2 to such a NOAA summary when reviewing historical weather station
3 locations and instrumentation?

4 A. Yes. In this instance, I reviewed Schedule 2 in the
5 course of preparing this testimony.

6 Q. According to the data contained in Schedule 2, have
7 the weather records at St. Louis been taken at the same location
8 throughout the time of record keeping?

9 A. No, the records were first taken at a location in the
10 center of the downtown area of St. Louis. Later, with the
11 establishment of the airport (Lambert Field) these responsibilities
12 were transferred to the airport location.

13 The downtown temperature observations were taken at roof-
14 top, about 200 feet above the street from 1903 onward until the closing
15 of the observing station in 1968. Prior to 1903, the roof-top station
16 was located about 100 feet above the street.

17 Unless one carefully reviews the station location
18 descriptions, it would appear that the Lambert Field Station did not
19 experience much of a change since it was established in 1929. There
20 are, however, two changes in the location of the instruments at Lambert
21 Field requiring analysis.

22 Q. What are these changes?

23 A. In November 1943 the site of the temperature
24 measurement at Lambert Field was moved from a position away from the
25 building (in an instrument shelter at five feet above the ground) to
26 a roof-top location on the second floor of the Administration Building.
27 This position allowed the dark roofing and the vents from the first
28 floor to provide a less than ideal location for documenting the climate
29 of the area. I have reviewed the degree day values reported for
30 Lambert Field for this period (1943 through September 1957) and these
31 records show the period as one with low heating degree day totals. The

Direct Testimony of
Wayne L. Decker

1 average degree days from the period extending from the 1943-44 season
2 through the 1956-57 season is some 61 lower than the mean of 4838
3 calculated for the period currently used by the Public Service
4 Commission. It is very likely that the warmer temperatures were, at
5 least in part, due to heat added by the roof exposure.

6 On April 18, 1958, the site of measurement at Lambert Field
7 was moved to a position between the runways and over grass. This move
8 may have resulted in a cooler environment than when the instruments
9 were located close to or on buildings.

10 Q. Have the weather records always been derived from the
11 same type of weather instruments in St. Louis?

12 A. For most of the period since the late 1890's the
13 temperature records have come from liquid in glass thermometers
14 (mercury or alcohol in glass). These thermometers were shaded from the
15 sun and protected from the earth's radiation by a louvered box mounted
16 about five feet above the ground or roof top.

17 However, when the instruments were moved to the runway
18 location at Lambert Field in April 1958, the system of measuring
19 temperatures employed by the National Weather Service in St. Louis was
20 changed. This change consisted of discontinuing the use of liquid
21 thermometers mounted in the white instrument shelter in favor of
22 electrical thermometers exposed in a reflective cylinder over the grass
23 areas between the runways. The observations from these instruments are
24 recorded on indicators in the National Weather Service Office. This
25 new system was installed at all airport observing stations of the
26 National Weather Service at about this same time. Since the
27 instruments were located away from the buildings and the paved tarmac,
28 the temperatures are typically cooler than those previously reported
29 from exposures near the buildings. This system has continued in use
30 for the past three decades. It can be noted that the heating degree
31 days in recent years (since 1960) are markedly higher, suggesting that

Direct Testimony of
Wayne L. Decker

1 the new location provides a sampling of temperatures for a slightly
2 cooler climate for the Lambert Field area. Even when one includes the
3 degree day totals for the warmer most recent decade (1981-82 through
4 1990-91) the thirty-two year average (1958-59 through 1990-91) is very
5 close to the value suggested by the Commission as the long-time
6 average.

7 Q. For describing the climatic characteristics does the
8 climatologist usually use the entire period of record available for a
9 particular station?

10 A. Climatologists tend to use a subset of the entire
11 period of record for describing the characteristics of the climate of
12 a city or region. The length of record for this subset should be long
13 enough to represent the climate of the region in a manner that reduces
14 the changes of a short sequence of cool or warm years influencing the
15 climatic statistics. Clearly the period should be long enough to be
16 "representative" of the climate of the region, but not be so long that
17 it measures a condition that has already past and no longer valid for
18 the climatological time series. This problem of defining a base period
19 for the "normal" climate has plagued climatologists for many years.
20 The World Meteorological Organization (a UN agency which coordinates
21 national programs in meteorology and climatology) and the National
22 Weather Service in the U. S. have adopted the policy of using the most
23 recent thirty-year period as the average for comparison purposes.
24 Under their policy, the average is "rolled over" at the beginning of
25 each decade. The newly established "normals" are then used for the
26 next ten years.

27 Q. Is using the "thirty year normals" better than using
28 the entire record available for St. Louis?

29 A. The climate of any region is dynamic in the sense
30 that there is a constant change. Some of these changes appear to be

Direct Testimony of
Wayne L. Decker

1 random while others are systematic. The "rolled over average" is used
2 for the normals to minimize the systematic errors.

3 One source of the systematic error is the change in the type
4 of instruments used to measure temperature and the exposure of these
5 instruments. It appears obvious that if a different procedure was
6 previously used for measuring temperature than is used today that the
7 older records should not be included in the base period which defines
8 the climatic normals.

9 Another systematic error in temperature is the changes
10 associated with the growth of the city of St. Louis. The "urban heat
11 island" is a well documented phenomenon which notes that the urban
12 temperatures are warmer than the nearby rural temperatures,
13 particularly at night. This temperature difference is related to size
14 of the city (area and population). The center of warming and the
15 extent of warming depends on the configuration of the city. In the
16 case of St. Louis, there has been some documentation of the urban
17 effect from detailed studies in the 1960's. It appears that the center
18 of development in St. Louis has been away from the Mississippi River,
19 and the urbanization of the area around Lambert Field is apparent. The
20 opportunity for an urban climate change in the Lambert Field weather
21 records, although not documented, is certainly present.

22 Q. What would you recommend the Commission use for the
23 "base period" in defining degree day normals for St. Louis?

24 A. I would recommend that the most recent thirty-year
25 period with a recalculation every decade be used for the following
26 reasons:

- 27 (1) It would not allow events which have occurred nearly
28 a century ago to be equally weighted with more
29 recent events in the calculation of the normals;
30 (2) It would allow for an adjustment for changes in
31 climate, both natural or anthropogenic;

Direct Testimony of
Wayne L. Decker

- 1 (3) this procedure would bring the techniques used in
2 Missouri in line with those used by the National
3 Weather Service and other States;
4 (4) the thirty-year period is long enough to produce
5 statistics that are stable without major variations
6 from decade to decade;
7 (5) during the most recent thirty-year period (1961-
8 1990), the observations at Lambert Field have been
9 taken from the same site using the same type of
10 weather instruments.

11 Q. Does that conclude your testimony?

12 A. Yes.

DIRECT TESTIMONY

OF

STEVE QI HU

LACLEDE GAS COMPANY

CASE NO. GR-99-315

Q. Please state your name and business address.

A. My name is "Steve" Qi Hu, and my business address is 237 L.W. Chase Hall,
University of Nebraska-Lincoln, Lincoln, Nebraska 68583-0728.

Q. What is your present position?

A. I am a climatologist and an Assistant Professor of Atmospheric Science at
the School of Natural Resource Sciences of the University of Nebraska-Lincoln.

Q. How long have you held your position and briefly describe your
responsibilities?

A. I was appointed to my present position in February 1999. My responsibilities
at this position include research, extension service and teaching. In research, I am
developing and improving our understanding of the regional climate variations and
climate impacts on regional agriculture and the regional economy. In extension service, I
am responsible for disseminating the most recent research results in climate and climate
variations to the general public of Nebraska and neighboring states including Missouri. In
teaching, I am currently teaching the Agricultural Climatology course.

Q. Do you have any previous work record in the State of Missouri?

Direct Testimony of
Steve Qi Hu

1 A. Yes. I was a Research Assistant Professor of Atmospheric Science at the
2 University of Missouri-Columbia, and served as the Missouri State Climatologist and
3 Director of the Missouri Climate Center for the time period July 1995 through January
4 1999.

5 Q. Could you briefly describe your responsibilities at that position?

6 A. I was developing research programs aimed at understanding the regional
7 climate variations and climate impacts on regional agriculture. In service as the State
8 Climatologist, I was responsible for archiving, maintaining, and disseminating weather
9 and climate data to the general public of Missouri. I was also responsible for providing
10 expert interpretations of weather and climate data to data users.

11 Q. What is your educational background?

12 A. I obtained my M.S. and Ph.D. degrees in Atmospheric Sciences from
13 Colorado State University in 1986 and 1992, respectively. I had my post-doctoral
14 training at the State University of New York-Albany from 1992 through 1994. Prior to
15 my M.S. degree, I obtained my B.S. degree in Meteorology from Lanzhou University in
16 China in 1982.

17 Q. Will you briefly describe your experience as a Climatologist?

18 A. My research in regional climate variations has produced many refereed
19 publications and numerous conference presentations. I have used various methods in
20 analyzing climatic data and understanding regional climate variations.

21 Q. What is the purpose of your testimony?

Direct Testimony of
Steve Qi Hu

1 A. I will explain the necessity for adjusting the station temperatures and a
2 procedure I used in correcting the Saint Louis Lambert International Airport station
3 temperature time series for the time period 1961-1998.

4 Q. What kind of weather station is at the Saint Louis Lambert International
5 Airport?

6 A. The Saint Louis Lambert International Airport station is a first-order weather
7 station of the U.S. National Weather Service and is operated by properly trained
8 professionals.

9 Q. Why do you need to adjust the observed temperature?

10 A. Adjustments of observed air temperature from an individual weather station
11 are needed to remove potential errors and biases in the temperature data.

12 Q. What possible errors could exist in the observed temperature values?

13 A. The errors in observed temperature data may be categorized into two groups.
14 1) The error resulting from observer's human error. This kind of error enters the data
15 when, for example, observers read incorrectly the scales of a thermometer or take the
16 observation at a time different from the specified observation time. 2) The error resulting
17 from malfunctioning thermometers falls into the second category.

18 Q. How do you find these errors and how do you correct them?

19 A. These errors are identified at the National Climatic Data Center at Asheville,
20 North Carolina, after the data are reported to the center. The data are checked using a
21 developed quality control method. Erroneous data is flagged and then an estimated value
22 is assigned to replace the erroneous data. The estimated value can be derived using
23 different methods.

Direct Testimony of
Steve Qi Hu

1 Q. What are potential biases in the observed temperature data?

2 A. There are two sources producing biases in the observed temperature data. 1)
3 The sensor bias. This is a bias due to systematic overestimate or underestimate of the
4 temperature by a thermometer. This kind of bias may be introduced to the data due to
5 drifting of aging sensors. 2) The bias resulting from physical environment change of the
6 weather station. These include station location changes and the surrounding environment
7 change as consequences of economic development, e.g., the new buildings and parking
8 areas, and natural change such as maturing trees. These changes alter the environment of
9 the station and, hence, the averaged thermal condition the station measures.

10 Q. What kind of biases have you found in the Saint Louis Lambert International
11 Airport weather station data, and what may have caused them?

12 A. I found that the station location change and consequent exposure changes
13 have caused systematic biases in the station temperature data. My investigation of the
14 station history of the Saint Louis Lambert International Airport station has disclosed that
15 the station location changed four times during the 38-year period of 1961-1998. These
16 occurred in November 1979, January 1985, February 1988, and June 1996. My analysis
17 revealed that two of the four location changes, i.e., the ones in 1979 and 1988, caused
18 systematic warming biases to the station temperature data and the change in 1996
19 resulted in a reversal of this warming bias.

20 Q. Why was a warming bias introduced to the data by the location changes in
21 November 1979 and February 1988?

22 A. The warming bias was introduced to the data because each of those two
23 location changes brought the station to a less open area. For example, in November 1979

Direct Testimony of
Steve Qi Hu

1 the thermometer was moved from a relatively open field to a new location very close to a
2 building with an improved parking area. The building and parking lot pavement absorb
3 solar radiation and emit long-wave radiation to warm the environment during the day.
4 The building also emits more heat during night. The thermal effect of the building and
5 the parking lot added a warming bias to the temperature data of the station. In June 1996,
6 the station was moved back to the airfield, where the thermal effects of the building and
7 the parking lot would no longer impact the temperature readings.

8 Q. What procedures have you used to correct the bias in the temperature data?

9 A. The procedures include the following: 1) identify the dates of the station
10 location change by reviewing the station history files and interviewing the observers
11 during visits to the station; 2) identify reference weather stations for which normals are
12 published and which did not experience location changes during the time when the Saint
13 Louis Lambert International Airport station was moved; 3) compare the temperature
14 series of the Saint Louis Lambert International Airport station and the reference stations
15 over the period covering the time of the station location change, and identify any bias
16 introduced to the Saint Louis Lambert International Airport station temperature record
17 from the station's location change; and 4) calculate the correction value and apply it to
18 the daily temperature series of the Saint Louis Lambert International Airport station to
19 remove the bias.

20 Q. What was the application of these procedures to correct for the location
21 changes at the St. Louis Lambert International Airport?

22 A. For the November 1979 and February 1988 changes, the reference stations
23 chosen were at Elsberry, MO and Unionville, MO. Five years of monthly maximum and

Direct Testimony of
Steve Qi Hu

1 monthly minimum temperatures were used to calculate the changes that had occurred at
2 the St. Louis Lambert International Airport. For the June 1996 change, five years of
3 consistent daily temperature series were available from the Elsberry, MO and Jerseyville,
4 IL weather stations. These data were used to calculate the changes that occurred at the
5 St. Louis Lambert International Airport weather station when the station was moved back
6 to the airfield and the ASOS was commissioned. Further details of the procedures and
7 data used are provided in my work papers.

8 Q. What are the differences between the uncorrected and corrected temperature
9 data?

10 A. The warming bias resulting from the November 1979 location change is
11 0.700°F. There was no bias added to the station temperature from the location change in
12 January 1985. My analysis revealed that the uncorrected temperature was warmer by
13 0.783°F as a result of the station being moved to a location close to a building and a
14 parking area in February 1988. The station location change in June 1996 was from a site
15 close to a building and a parking area to an open area (see Figure 2 on Schedule 1-8).
16 This location change was accompanied with the observation system change from the
17 conventional unit to the ASOS (Automated Surface Observation System). This change in
18 location resulted in a reversal of the warming bias of -1.875°F. The net effect for the
19 three changes is that the post June 1996 temperatures will read 0.392°F cooler than
20 temperatures read prior to November 1979. This is within the ASOS cooling bias of
21 0.5°F found by climatologist Thomas McKee ["Climate Data Continuity Project Ends:"
22 Silver Spring, MD 20910, ASOS Program Office Wx23, 8455 Coleville Rd., Suite 705].

Direct Testimony of
Steve Qi Hu

1 Q. How could these differences be affecting the calculated heating degree days
2 and cooling degree days using the uncorrected Saint Louis Lambert International Airport
3 temperature data?

4 A. Because the heating degree days are defined as the summation of the
5 differences of the actual temperature below a reference temperature, e.g., 65°F, in each
6 hour during each day and over a one year period, a warming bias in observed temperature
7 will lower the difference between the reference and the observed temperatures and,
8 hence, reduce the total number of heating degree days in a year. The opposite effect will
9 occur for cooling degree days. In this case, the warming bias in the Saint Louis Lambert
10 International Airport station temperature data can cause a decrease in the number of
11 heating degree days and an increase in cooling degree days recorded at the station.

12 Q. Did you provide these corrections for the Saint Louis Lambert International
13 Airport station to Mr. Dennis Patterson for use in calculating normal heating degree
14 days?

15 A. Yes, Mr. Patterson used these corrections in his calculation of normal heating
16 degree days for the Saint Louis Lambert International Airport station.

17 Q. What should be a time period for developing meaningful climate normals?

18 A. In describing climate "normals" the WMO (World Meteorological
19 Organization) requires the use of 30-year temperature and precipitation data. This
20 standard is accepted by the U.S. National Weather Service. One of the reasons for using
21 such a time period in defining climate conditions is that climate has its natural
22 variabilities. These variabilities are shown, in part, by oscillatory variations of
23 temperature and precipitation at various time periods. For example, there have been

Direct Testimony of
Steve Qi Hu

1 many studies showing significant interannual and interdecadal temperature variations in
2 the U.S. To minimize the impacts of these fluctuations on averaged climate conditions
3 WMO recommends to use 30-year data in calculation of the normal of the surface air
4 temperature.

5 Q. Does this conclude your direct testimony?

6 A. Yes it does.

On December 2, 1996, Riverside/Mid-Kansas filed a motion to strike a portion of late-filed Exhibit 172. Riverside/Mid-Kansas requests that the portion beginning with page 3, line 7, through the bottom of page 4, be stricken, because it goes beyond the information requested by Commissioner Crumpton.

On December 10, 1996, MGE filed a response to the motion to strike. MGE argues that all of late-filed Exhibit 172 is responsive to Commissioner Crumpton's request.

The Commission finds that all of Exhibit 172 is responsive to Commissioner Crumpton's request. The Commission will deny the motion to strike.

The Commission has received no objections to the receipt of the late-filed exhibits other than the objection of Riverside/Mid-Kansas discussed above.

Late-filed Exhibits 113, 114, 115, 116, 117, 120, 163, 163HC, 164, 171, 172, 173, 174, 179 and 179HC shall be received into the record.

Findings of Fact

The Missouri Public Service Commission, having considered all of the competent and substantial evidence upon the whole record, makes the following findings of fact.

I. Revenue Adjustments

A. Weather Normalization Adjustment

This issue concerns the appropriate period of time to use for the purpose of establishing "normal" temperatures in the context of setting rates for MGE. MGE advocates the use of ten years of data ending March 31, 1996. Staff advocates the use of 30 years of data (1961 through 1990). Public Counsel agrees with the Staff on this issue.

MGE witness Cummings maintains that the ten-year average of Heating Degree Days (HDD) compiled by the National Oceanographic and Atmospheric Administration (NOAA) better reflects the temperatures experienced in recent years and is not influenced by several consecutive cold winters which occurred many years ago and have not repeated themselves. (Ex. 9, p. 8). Dr. Cummings performed an analysis where he calculated the median temperatures over the last ten and fifteen years and he concluded that the ten-year measure is more representative of recent years' temperatures than the use of the 1961-1990 measure. (Ex. 9, p. 9). The reason for this result is that there were some winters with extremely cold temperatures a number of years ago that are reflected in the 30-year measure, and these extremes have not repeated themselves in the last decade. (Ex. 9, p. 10).

Staff maintains that the Commission should use the 30-year measure of normal temperatures published by NOAA, which are based on properly adjusted monthly Heating Degree Day data from the FAA weather stations at Kansas City International Airport and the Joplin Airport. Staff argues that the 30-year average is the more proper measure of "normal weather" rather than the ten-year moving average proposed by the Company. NOAA's 30-year normal averages are compiled independently of the regulatory process and are set for a period of ten years at a time after each decade of data can be analyzed. The calculations of "normals" are done only once every ten years because they require a substantial effort and commitment of NOAA's resources. The published normals used by Staff remain the same for those ten years until another decade's worth of data is collected and analyzed by NOAA.

Staff believes that the 30-year period utilized by NOAA is necessary to constitute a normal period. This period is long enough to compensate for shorter-term cycles that may be present in the data, while not being so long that

historical conditions which are no longer relevant might influence the calculations of normals. Staff maintains that the use of a ten-year moving average as proposed by MGE results in great fluctuations of "normals" which has no place in setting rates on a forward-looking basis.

The Commission finds that NOAA's 30-year normals is the more appropriate benchmark. The ten-year moving average would needlessly cause frequent rate changes based on the introduction of new data every year. If one takes MGE's argument to its logical extreme, the Commission would use the most recent year's experience in MGE's service territory and re-set rates each year. This could lead to serious financial problems for MGE if its rates were set after a record-setting cold year. In addition, the data upon which Staff's recommendation is based has gone through the processes established by NOAA to ensure the best data possible. This safeguard is not present in MGE's approach.

B. Economic Development Discounts

OPC maintains that the Commission must impute the full level of revenues based on the Large Volume contract rate. OPC bases this position on the tariff language contained on MGE's Sheet 74, which states:

Prior to any determination of the Company's revenue requirement for rate making purposes before the Commission, test year revenues shall first be adjusted to the level corresponding to that which would be produced under the standard Large Volume contract rate schedule with respect to the customers qualified for service hereunder.

OPC maintains that this language precludes Staff and MGE from making their recommended adjustment that has the effect of having ratepayers fund approximately 25 percent of the amount of economic development discounts.

This issue is the extent to which MGE's shareholders should bear the cost associated with discounted rates which MGE offers under MGE's economic

Company Name	MO PSC Staff-(All)
Case/Tracking No.	GR-2006-0422
Date Requested	10/17/2006
Issue	Revenue - Weather Normalization
Requested From	Curt Wells
Requested By	Michael R Noack
Brief Description	NA
Description	Define the term "weather normal" as understood by Mr. Wells within the context of his direct testimony.
Due Date	11/6/2006

Response:

Mr. Wells understands "Weather normal" in this context to be, as defined by NOAA and the WMO, the arithmetic average of a weather variable-- in this case daily average temperature (the arithmetic average of the day's maximum and minimum) over the 30-year period from Jan 1, 1971 through December 31, 2000.

Data Request

Data Request No.	0211
Company Name	MO PSC Staff-(All)
Case/Tracking No.	GR-2006-0422
Date Requested	10/17/2006
Issue	Revenue - Weather Normalization
Requested From	Curt Wells
Requested By	Michael R Noack
Brief Description	NA
Description	Would Mr. Wells agree that the choice of a weather normal for MGE should best reflect the weather expected to occur when its approved rates in this case go into effect? If not, please fully explain the factors he believes should be considered in choosing a weather normal for a gas utility such as MGE.
Due Date	11/6/2006

Response:

No, Mr. Wells does not agree because Missouri is a test year state. In Missouri, utility sales data from a test year are adjusted for departures from the normal condition in order to calculate a revenue requirement and a set of rates for a year where the normal condition would have been experienced. The weather normal chosen should be sufficiently long to provide the necessary stability without major variations, yet not excessively long to inappropriately weight long past values collected with now obsolete instruments using different procedures. NOAA and the WMO have determined that the three-decade normal period with updates each ten years meets these requirements.

Missouri Public Service Commission

Data Request

Data Request No.	0212
Company Name	MO PSC Staff-(All)
Case/Tracking No.	GR-2006-0422
Date Requested	10/17/2006
Issue	Revenue - Weather Normalization
Requested From	Curt Wells
Requested By	Michael R Noack
Brief Description	NA
Description	Has Mr. Wells in this proceeding conducted any specific analysis to determine the most appropriate weather predictor to normalize MGE's annual customer loads for weather? If not, please fully explain why such an analysis has not been conducted.
Due Date	11/6/2006

Response:

The analysis performed was to determine the appropriate weather stations to which to apply the 30-year normal. As stated in the response to DR 211, Missouri is a test year state. Sales data from a test year are adjusted for departures from the normal condition to calculate a revenue requirement and set of rates for a year in which the normal condition would have been experienced. The test year is compared to a "normal" year. No attempt is made to "predict" future weather.

Previous analyses, listed in response to DR 209, have shown that the NOAA/WMO 30-year normals period is the most appropriate time frame for determination of a normal. Customer loads are based on Heating Degree Days, defined as the number of degrees daily average temperature is below a 65 degree base. These loads are compared to the normal daily heating degree days defined using the NOAA 30-year period.
