DIRECT TESTIMONY

OF

SAMUEL C. HADAWAY

I. INTRODUCTION AND SUMMARY OF RECOMMENDATIONS

Q. Please state your name and business address.

A. My name is Samuel C. Hadaway and my business address is FINANCO, Inc., 3520 Executive Center Drive, Austin, Texas 78731.

Q. On whose behalf are you testifying?

A. I am testifying on behalf of Kansas City Power & Light Company ("KCP&L" or the "Company").

Q. Please state your educational background and describe your professional training and experience.

A. I have a bachelor's degree in economics from Southern Methodist University, as well as M.B.A. and Ph.D. degrees with concentrations in finance and economics from the University of Texas at Austin ("UT Austin"). For the past 25 years, I have been an owner and full-time employee of FINANCO, Inc. FINANCO provides financial research concerning the cost of capital and financial condition for regulated companies as well as financial modeling and other economic studies in litigation support. In addition to my work at FINANCO, I have served as an adjunct professor in the McCombs School of Business at UT Austin and in what is now the McCoy College of Business at Texas State University. In my prior academic work, I taught economics and finance courses and I conducted research and directed graduate students in the areas of investments and capital market research. I was previously

Director of the Economic Research Division at the Public Utility Commission of Texas where I supervised the Commission's finance, economics, and accounting staff, and served as the Commission's chief financial witness in electric and telephone rate cases. I have taught courses at various utility conferences on cost of capital, capital structure, utility financial condition, and cost allocation and rate design issues. I have made presentations before the New York Society of Security Analysts, the National Rate of Return Analysts Forum, and various other professional and legislative groups. I have served as a vice president and on the board of directors of the Financial Management Association.

A list of my publications and testimony I have given before various regulatory bodies and in state and federal courts is contained in my resume, which is included as Appendix A.

Q. Have you previously testified in a proceeding at the Missouri Public Service Commission or before any other utility regulatory agency?

A. Yes, I have. I have testified before the Missouri Public Service Commission and numerous other state commissions on ROE and related financial issues.

Q. What is the purpose of your testimony?

A. The purpose of my testimony is to estimate KCP&L's required rate of return on equity ("ROE") and to support the Company's requested capital structure and overall rate of return.

Q. Please outline and describe the testimony you will present.

A. My testimony is divided into four additional sections. Following this introduction, in Section II, I present and explain the Company's requested capital structure and overall

cost of capital. In Section III, I review various methods for estimating the cost of equity. In this section, I discuss the discounted cash flow ("DCF") model, as well as risk premium methods and other approaches often used to estimate the cost of capital. In Section IV, I review general capital market costs and conditions, and discuss recent developments in the electric utility industry that affect the cost of capital. In Section V, I discuss the details of my cost of equity studies and provide a summary table of my ROE results.

Q. Please describe the general approach in your cost of equity studies.

A. First, my recommendation is premised upon the fair rate of return principles established by the U.S. Supreme Court in *Federal Power Comm'n v. Hope Natural Gas Co.,* 320 US 591, 603 (1944) ("*Hope*") and *Bluefield Water Works & Improvements Co. v. Public Service Commission,* 262 US 679, 693 (1923) ("*Bluefield*"). That is to say, a utility's return authorized by a regulatory body, such as the Missouri Public Service Commission, should be commensurate with returns on investments in other enterprises having corresponding risks. The return should also be sufficient to assure confidence in the financial integrity of the utility so as to maintain its credit, and to attract capital so that it is able to properly discharge its public duties. Given these legal principles, I have used several methods to determine an appropriate ROE and overall rate of return for KCP&L. These methods and the underlying economic models are applied to an investment grade company reference group of other electric utilities generally similar to KCP&L.

Q. Please explain your analysis in arriving at a recommended ROE for KCP&L.

A. My ROE estimate is based on alternative versions of the constant growth and multistage growth DCF model. It is confirmed by my risk premium analysis and my review of economic conditions and interest rates expected to prevail during the coming year. Because KCP&L is a wholly-owned subsidiary of Great Plains Energy Incorporated ("GPE") and does not have publicly traded common stock or other independent market data, its cost of equity cannot be estimated directly. For this reason, I apply the DCF model to a large reference group of investment grade electric utilities selected from the *Value Line Investment Survey*. To be included in my group, the reference companies must have at least a triple-B (investment grade) bond rating; they must derive at least 70 percent of revenues from regulated utility sales; they must have consistent financial records not affected by recent mergers or restructuring; and they must have a consistent dividend record with no dividend cuts within the past two years. The companies in my comparable group are summarized in Schedule SCH-1.

To test my DCF results, I conducted a risk-premium analysis based on ROEs allowed by state regulators relative to Moody's average utility debt costs. In this analysis, I also included the forecasted higher interest rates of Standard and Poor's ("S&P") for the coming year. S&P forecasts that long-term Government and corporate interest rates will increase from current levels by 40 to 50 basis points during 2009. Under current market and economic conditions, the combination of DCF and risk premium models, tempered by consensus forecasts about future interest rates, provides the best approach for estimating KCP&L's fair cost of equity capital.

Q. What ROE range is indicated by your DCF and risk premium analyses?

A. My reference group analysis indicates that a DCF range of 10.8 percent to 11.2 percent is appropriate. My risk premium analysis, which serves as a check of reasonableness for the DCF results, indicates that an ROE of 11.10 percent is appropriate, with other risk premium approaches indicating an ROE of 11.49 percent.

Q. What are your overall conclusions from your ROE analysis?

A. Based on the combination of quantitative model results and my review of current economic, market, and electric utility industry conditions, I estimate KCP&L's cost of equity at 10.75 percent. This estimate is consistent with capital market trends and projections and is a reasonable estimate of capital costs that will prevail during the period that the rates from this case are in effect.

II. KCP&L CAPITAL STRUCTURE AND OVERALL RATE OF RETURN

Q. Please summarize the Company's requested capital structure and overall rate of return.

A. The following table identifies the requested capital structure components and the resulting overall rate of return:

Requested Capital Structure

Capital Components	Ratio	Cost	Weighted Cost
Debt	45.47%	6.32%	2.87%
Preferred stock	0.71%	4.29%	0.03%
Common Equity	53.82%	10.75%	5.79%
TOTAL	100.00%		8.69%

Q. What is the basis for the Company's requested capital structure and overall rate of return?

A. The requested capital structure is consistent with Great Plains Energy's projected capital structure at March 31, 2009. These data are presented in more detail in Schedule SCH-2, with the March 31, 2009 summary shown on page 6 of that

schedule. Using the parent company's consolidated capital structure is consistent with KCP&L's approach in its 2006 and 2007 rate cases.

Q. What are the key differences between Great Plains Energy's actual capital structure as of December 31, 2007 and the requested capital structure, projected as of March 31, 2009?

A. The actual Great Plains Energy capital structure as of December 31, 2007, is shown on page 2 of Schedule SCH-2. The key differences between the actual capital structure and the requested capital structure, projected as of March 31, 2009, are as follows:

Long-Term Debt

Net Long-Term Debt is projected to increase by $1,397 million, the largest components of which consist of the following:

(a) KCP&L issued $350 million of 10-year senior unsecured notes in March 2008 to finance construction expenditures.

(b) KCP&L issued $23.4 million of EIRR bonds in May 2008 to finance a portion of the Company's qualifying environmental equipment at Iatan 1 and 2.

(c) Great Plains acquired Aquila in July 2008 which will have a projected outstanding debt balance of $1,023 million as of March 2009.

Equity

Equity is projected to increase by **[redacted]** million, the largest components of which are as follows:

(a) **[redacted]** million in additional equity issued through public offerings by Great Plains Energy.

(b) Approximately $1,026 million of equity issued by Great Plains Energy related to the Aquila acquisition.

III. ESTIMATING THE COST OF EQUITY CAPITAL

Q. What is the purpose of this section of your testimony?

A. The purpose of this section of my testimony is to present a general definition of the cost of equity and to compare the strengths and weaknesses of several of the most widely used methods for estimating the cost of equity. Estimating the cost of equity is fundamentally a matter of informed judgment. The various models provide a concrete link to actual capital market data and assist with defining the various relationships that underlie the ROE estimation process.

Q. Please define the term "cost of equity capital" and provide an overview of the cost estimation process.

A. The cost of equity capital is the profit or rate of return that equity investors expect to receive. In concept it is no different than the cost of debt or the cost of preferred stock. The cost of equity is the rate of return that common stockholders expect, just as interest on bonds and dividends on preferred stock are the returns that investors in those securities expect. Equity investors expect a return on their capital commensurate with the risks they take, consistent with returns that are available from other similar investments. Unlike returns from debt and preferred stocks, however, the equity return is not directly observable in advance and, therefore, it must be estimated or inferred from capital market data and trading activity.

An example helps to illustrate the cost of equity concept. Assume that an investor buys a share of common stock for $20 per share. If the stock's expected

dividend is $1.00, the expected dividend yield is 5.00 percent ($1.00 / $20 = 5.0 percent). If the stock price is also expected to increase to $21.20 after one year, this $1.20 expected gain adds an additional 6.0 percent to the expected total rate of return ($1.20 / $20 = 6.0 percent). Therefore, when buying the stock at $20 per share, the investor expects a total return of 11.00 percent: 5.0 percent dividend yield, plus 6.0 percent price appreciation. In this example, the total expected rate of return at 11.00 percent is the appropriate measure of the cost of equity capital, because it is this rate of return that caused the investor to commit the $20 of equity capital in the first place. If the stock were riskier, or if expected returns from other investments were higher, investors would require a higher rate of return from the stock, which would result in a lower initial purchase price in market trading.

Each day market rates of return and prices change to reflect new investor expectations and requirements. For example, when interest rates on bonds and savings accounts rise, utility stock prices usually fall. This is true, at least in part, because higher interest rates on these alternative investments make utility stocks relatively less attractive, which causes utility stock prices to decline in market trading. This competitive market adjustment process is quick and continuous, so that market prices generally reflect investor expectations and the relative attractiveness of one investment versus another. In this context, to estimate the cost of equity one must apply informed judgment about the relative risk of the company in question and knowledge about the risk and expected rate of return characteristics of other available investments as well.

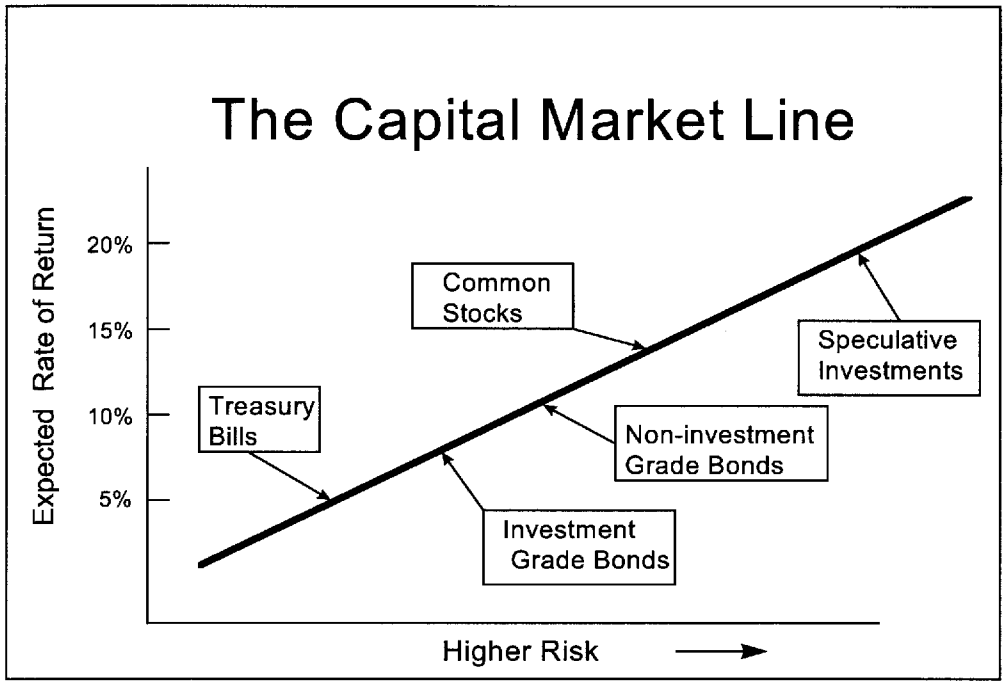
Q. How does the market account for risk differences among the various investments?

A. Risk-return tradeoffs among capital market investments have been the subject of extensive financial research. Literally dozens of textbooks and hundreds of academic articles have addressed the issue. Generally, such research confirms the common sense conclusion that investors will take additional risks only if they expect to receive a higher rate of return. Empirical tests consistently show that returns from low risk securities, such as U.S. Treasury bills, are the lowest; that returns from longer-term Treasury bonds and corporate bonds are increasingly higher as risks increase; and, generally, returns from common stocks and other more risky investments are even higher. These observations provide a sound theoretical foundation for both the DCF and risk premium methods for estimating the cost of equity capital. These methods attempt to capture the well founded risk-return principle and explicitly measure investors' rate of return requirements.

Q. Can you illustrate the capital market risk-return principle that you just described?

A. Yes. The following graph depicts the risk-return relationship that has become widely known as the Capital Market Line ("CML"). The CML offers a graphical representation of the capital market risk-return principle. The graph is not meant to illustrate the actual expected rate of return for any particular investment, but merely to illustrate in a general way the risk-return relationship.

Risk-Return Tradeoffs



As a continuum, the CML can be viewed as an available opportunity set for investors. Those investors with low risk tolerance or investment objectives that mandate a low risk profile should invest in assets depicted in the lower left-hand portion of the graph. Investments in this area, such as Treasury bills and short-maturity, high quality corporate commercial paper, offer a high degree of investor certainty. In nominal terms (before considering the potential effects of inflation), such assets are virtually risk-free.

Investment risks increase as one moves up and to the right along the CML. A higher degree of uncertainty exists about the level of investment value at any point in time and about the level of income payments that may be received. Among these

investments are long-term bonds and preferred stocks, which offer priority claims to assets and income payments. They are relatively low risk, but they are not risk-free. The market value of long-term bonds, even those issued by the U.S. Treasury, often fluctuates widely when government policies or other factors cause interest rates to change.

Farther up the CML continuum, common stocks are exposed to even more risk, depending on the nature of the underlying business and the financial strength of the issuing corporation. Common stock risks include market-wide factors, such as general changes in capital costs, as well as industry and company specific elements that may add further to the volatility of a given company's performance. As I will illustrate in my risk premium analysis, common stocks typically are more volatile and have higher risk than high quality bond investments and, therefore, they reside above and to the right of bonds on the CML graph. Other more speculative investments, such as stock options and commodity futures contracts, offer even higher risks (and higher potential returns). The CML's depiction of the risk-return tradeoffs available in the capital markets provides a useful perspective for estimating investors' required rates of return.

Q. How is the fair rate of return in the regulatory process related to the estimated cost of equity capital?

A. The regulatory process is guided by fair rate of return principles established in the U.S. Supreme Court cases, *Bluefield* and *Hope*:

> A public utility is entitled to such rates as will permit it to earn a return on the value of the property which it employs for the convenience of the public equal to that generally being made at the same time and in the same general part of the country on investments in other business

> undertakings which are attended by corresponding risks and uncertainties; but it has no constitutional right to profits such as are realized or anticipated in highly profitable enterprises or speculative ventures. *Bluefield Water Works & Improvement Company v. Public Service Commission of West Virginia*, 262 U.S. 679, 692-693 (1923).
>
> From the investor or company point of view, it is important that there be enough revenue not only for operating expenses, but also for the capital costs of the business. These include service on the debt and dividends on the stock. By that standard the return to the equity owner should be commensurate with returns on investments in other enterprises having corresponding risks. That return, moreover, should be sufficient to assure confidence in the financial integrity of the enterprise, so as to maintain its credit and to attract capital. *Federal Power Commission v. Hope Natural Gas Co.*, 320 U.S. 591, 603 (1944).

Based on these principles, the fair rate of return should closely parallel investor opportunity costs as discussed above. If a utility earns its market cost of equity, neither its stockholders nor its customers should be disadvantaged.

Q. What specific methods and capital market data are used to evaluate the cost of equity?

A. Techniques for estimating the cost of equity normally fall into three groups: comparable earnings methods, risk premium methods, and DCF methods.

Q. Please describe the first set of estimation techniques, the comparable earnings methods.

A. The comparable earnings methods have evolved over time. The original comparable earnings methods were based on book accounting returns. This approach developed ROE estimates by reviewing accounting returns for unregulated companies thought to have risks similar to those of the regulated company in question. These methods have generally been rejected because they assume that the unregulated group is earning its actual cost of capital, and that its equity book value is the same as its market value.

In most situations these assumptions are not valid, and, therefore, accounting-based methods do not generally provide reliable cost of equity estimates.

More recent comparable earnings methods are based on historical stock market returns rather than book accounting returns. While this approach has some merit, it too has been criticized because there can be no assurance that historical returns actually reflect current or future market requirements. Also, in practical application, earned market returns tend to fluctuate widely from year to year. For these reasons, a current cost of equity estimate (based on the DCF model or a risk premium analysis) is usually required.

Q. Please describe the second set of estimation techniques, the risk premium methods.

A The risk premium methods begin with currently observable market returns, such as yields on government or corporate bonds, and add an increment to account for the additional equity risk. The capital asset pricing model ("CAPM") and arbitrage pricing theory ("APT") model are more sophisticated risk premium approaches. The CAPM and APT methods estimate the cost of equity directly by combining the "risk-free" government bond rate with explicit risk measures to determine the risk premium required by the market. Although these methods are widely used in academic cost of capital research, their additional data requirements and their potentially questionable underlying assumptions have detracted from their use in most regulatory jurisdictions. The basic risk premium methods provide a useful parallel approach with the DCF model and assure consistency with other capital market data consistency in the cost of equity cost estimation process.

Q. Please describe the third set of estimation techniques, based on the DCF model.

A. The DCF model is the most widely used regulatory cost of equity estimation method. Like the risk premium approach, the DCF model has a sound basis in theory, and many argue that it has the additional advantage of simplicity. I will describe the DCF model in detail below, but in essence its estimate of ROE is simply the sum of the expected dividend yield and the expected long-term dividend (or price) growth rate. While dividend yields are easy to obtain, estimating long-term growth is more difficult. Because the constant growth DCF model also requires very long-term growth estimates (technically to infinity), some argue that its application is too speculative to provide reliable results, resulting in the preference for the multistage growth DCF analysis.

Q. Of the three estimation methods, which do you believe provides the most reliable results?

A. From my experience, a combination of discounted cash flow and risk premium methods provides the most reliable approach. While the caveat about estimating long-term growth must be observed, the DCF model's other inputs are readily obtainable, and the model's results typically are consistent with capital market behavior. The risk premium methods provide a good parallel approach to the DCF model and further ensure that current market conditions are accurately reflected in the cost of equity estimate.

Q. Please explain the DCF model.

A. The DCF model is predicated on the concept that stock prices represent the present value or discounted value of all future dividends that investors expect to receive. In the most general form, the DCF model is expressed in the following formula:

$$P_0 = D_1/(1+k) + D_2/(1+k)^2 + ... + D_\infty/(1+k)^\infty \qquad (1)$$

where P_0 is today's stock price; D_1, D_2, etc. are all future dividends and k is the discount rate, or the investor's required rate of return on equity. Equation (1) is a routine present value calculation based on the assumption that the stock's price is the present value of all dividends expected to be paid in the future.

Under the additional assumption that dividends are expected to grow at a constant rate "g" and that k is strictly greater than g, equation (1) can be solved for k and rearranged into the simple form:

$$k = D_1/P_0 + g \qquad (2)$$

Equation (2) is the familiar constant growth DCF model for cost of equity estimation, where D_1/P_0 is the expected dividend yield and g is the long-term expected dividend growth rate.

Q. Are there circumstances where the constant growth model may not give reliable results?

A. Yes. Under circumstances when growth rates are expected to fluctuate or when future growth rates are highly uncertain, the constant growth model may not give reliable results. Although the DCF model itself is still valid, i.e., equation (1) is mathematically correct, under such circumstances the simplified form of the model must be modified to capture market expectations accurately.

Recent events and current market conditions in the electric utility industry as discussed later appear to challenge the constant growth assumption of the traditional DCF model. Since the mid-1980s, dividend growth expectations for many electric utilities have fluctuated widely. In fact, over one-third of the electric utilities in the U.S. have reduced or eliminated their common dividends over this time period. Some of these companies have re-established their dividends, producing exceptionally high growth rates. Under these circumstances, long-term growth rate estimates may be highly uncertain, and estimating a reliable "constant" growth rate for many companies is often difficult.

Q. Can the DCF model be applied when the constant growth assumption is violated?

A. Yes. When growth expectations are uncertain, the more general version of the model represented in equation (1) should be solved explicitly over a finite "transition" period while uncertainty prevails. The constant growth version of the model can then be applied after the transition period, under the assumption that more stable conditions will prevail in the future. There are two alternatives for dealing with the nonconstant growth transition period.

Under the "terminal price" nonconstant growth approach, equation (1) is written in a slightly different form:

$$P_0 = D_1/(1+k) + D_2/(1+k)^2 + ... + P_T/(1+k)^T \qquad (3)$$

where the variables are the same as in equation (1) except that P_T is the estimated stock price at the end of the transition period T. Under the assumption that normal growth resumes after the transition period, the price P_T is then expected to be based

on constant growth assumptions. With the terminal price approach, the estimated cost of equity, k, is just the rate of return that investors would expect to earn if they bought the stock at today's market price, held it and received dividends through the transition period (until period T), and then sold it for price P_T. In this approach, the analyst's task is to estimate the rate of return that investors expect to receive given the current level of market prices they are willing to pay.

Q. What is the other alternative for dealing with the nonconstant growth transition period?

A. Under the "multistage" nonconstant growth approach, equation (1) is simply expanded to incorporate two or more growth rate periods, with the assumption that a permanent constant growth rate can be estimated for some point in the future:

$$P_0 = D_0(1+g_1)/(1+k) + \ldots + D_0(1+g_2)^n/(1+k)^n +$$
$$\ldots + (D_0(1+g_T)^{(T+1)}/(k-g_T))/(1+k)^T \qquad (4)$$

where the variables are the same as in equation (1), but g_1 represents the growth rate for the first period, g_2 for a second period, and g_T for the period from year T (the end of the transition period) to infinity. The first two growth rates are simply estimates for fluctuating growth over "n" years (typically 5 or 10 years) and g_T is a constant growth rate assumed to prevail forever after year T. The difficult task for analysts in the multistage approach is determining the various growth rates for each period.

Although less convenient for exposition purposes, the nonconstant growth models are based on the same valid capital market assumptions as the constant growth version. The nonconstant growth approach simply requires more explicit data inputs and more work to solve for the discount rate, k. Fortunately, the required data

are available from investment and economic forecasting services, and computer algorithms can easily produce the required solutions. Both constant and nonconstant growth DCF analyses are presented in the following section.

Q. Please explain the risk premium methodology.

A. Risk premium methods are based on the assumption that equity securities are riskier than debt and, therefore, that equity investors require a higher rate of return. This basic premise is well supported by legal and economic distinctions between debt and equity securities, and it is widely accepted as a fundamental capital market principle. For example, debt holders' claims to the earnings and assets of the borrower have priority over all claims of equity investors. The contractual interest on mortgage debt must be paid in full before any dividends can be paid to shareholders, and secured mortgage claims must be fully satisfied before any assets can be distributed to shareholders in bankruptcy. Also, the guaranteed, fixed-income nature of interest payments makes year-to-year returns from bonds typically more stable than capital gains and dividend payments on stocks. All these factors demonstrate the more risky position of stockholders and support the equity risk premium concept.

Q. Are risk premium estimates of the cost of equity consistent with other current capital market costs?

A. Yes. The risk premium approach is especially useful because it is founded on current market interest rates, which are directly observable. This feature assures that risk premium estimates of the cost of equity begin with a sound basis, which is tied directly to current capital market costs.

Q. Is there similar consensus about how risk premium data should be employed?

A. No. In regulatory practice, there is often considerable debate about how risk premium data should be interpreted and used. Since the analyst's basic task is to gauge investors' required returns on long-term investments, some argue that the estimated equity spread should be based on the longest possible time period. Others argue that market relationships between debt and equity from several decades ago are irrelevant and that only recent debt-equity observations should be given any weight in estimating investor requirements. There is no consensus on this issue. Since analysts cannot observe or measure investors' expectations directly, it is not possible to know exactly how such expectations are formed or, therefore, to know exactly what time period is most appropriate in a risk premium analysis.

The important point is to answer the following question: "What rate of return should equity investors reasonably expect relative to returns that are currently available from long-term bonds?" The risk premium studies and analyses I discuss later address this question. My risk premium recommendation is based on an intermediate position that avoids some of the problems and concerns that have been expressed about both very long and very short periods of analysis with the risk premium model.

Q. Please summarize your discussion of cost of equity estimation techniques.

A. Estimating the cost of equity is one of the most controversial issues in utility ratemaking. Because actual investor requirements are not directly observable, several methods have been developed to assist in the estimation process. The comparable earnings method is the oldest but perhaps least reliable. Its use of accounting rates of

return, or even historical market returns, may or may not reflect current investor requirements. Differences in accounting methods among companies and issues of comparability also detract from this approach.

The DCF and risk premium methods have become the most widely accepted in regulatory practice. A combination of the DCF model and a review of risk premium data provides the most reliable cost of equity estimate. While the DCF model does require judgment about future growth rates, the dividend yield is straightforward, and the model's results are generally consistent with actual capital market behavior. For these reasons, I will rely on a combination of the DCF model and a risk premium analysis in the cost of equity studies that follow.

IV. FUNDAMENTAL FACTORS THAT AFFECT THE COST OF EQUITY

Q. What is the purpose of this section of your testimony?

A. In this section, I review recent capital market conditions and industry and company-specific factors that should be reflected in the cost of capital estimate.

Q. What has been the recent experience in the U.S. capital markets?

A. Schedule SCH-3, page 1, provides a review of annual interest rates and rates of inflation in the U.S. economy over the past ten years. During that time inflation and fixed income market costs declined and, generally, have been lower than rates that prevailed in the previous decade. Inflation, as measured by the Consumer Price Index ("CPI"), until 2003 had remained at historically low levels not seen consistently since the early 1960s. Since 2003, however, inflation rates have increased with the average for 2004 though 2006 similar to the longer-term historical average, which is above 3 percent. The inflation rate for 2007 was even higher at 4.1 percent and, with the large

recent increases in energy and food prices, for the twelve months ended July 2008, the CPI increased 5.6 percent. These inflationary pressures exert a direct influence on capital market expectations and result in a higher cost of capital.

The Federal Reserve System's monetary policy options are currently limited by rising inflation and simultaneously weak economic conditions. During the period from mid-2004 until mid-2006, the Federal Reserve System increased the short-term Federal Funds interest rate 17 times, raising it from 1 percent to 5.25 percent. In late 2007, in response to the extreme turbulence in the sub-prime credit markets, the Federal Reserve Open Market Committee began aggressively reducing the Federal Funds rate. Since September 2007, the rate has been lowered seven times to its current level of 2.0 percent. With rising inflation expectations, however, and low market tolerance for additional risk, long-term corporate interest rates have not declined over the past two years. Furthermore, estimates for the coming year are for additional interest rate increases.

Q. How have long-term interest rates changed over the past two years?

A. The following table, which also appears on page 2 of Schedule SCH-3, provides the month-by-month interest rates paid by utilities and the U.S. Treasury:

Table 1
Long-Term Interest Rate Trends

Month	Triple-B Utility Rate	30-Year Treasury Rate	Triple-B Utility Spread
Jan-06	6.06	ND	ND
Feb-06	6.11	4.54	1.57
Mar-06	6.26	4.73	1.53
Apr-06	6.54	5.06	1.48
May-06	6.59	5.20	1.39
Jun-06	6.63	5.15	1.48
Jul-06	6.63	5.13	1.50
Aug-06	6.43	5.00	1.43
Sep-06	6.26	4.85	1.41
Oct-06	6.24	4.85	1.39
Nov-06	6.04	4.69	1.35
Dec-06	6.05	4.68	1.37
Jan-07	6.16	4.85	1.31
Feb-07	6.10	4.82	1.28
Mar-07	6.10	4.72	1.38
Apr-07	6.24	4.87	1.37
May-07	6.23	4.90	1.33
Jun-07	6.54	5.20	1.34
Jul-07	6.49	5.11	1.38
Aug-07	6.51	4.93	1.58
Sep-07	6.45	4.79	1.66
Oct-07	6.36	4.77	1.59
Nov-07	6.27	4.52	1.75
Dec-07	6.51	4.53	1.98
Jan-08	6.35	4.33	2.02

Sources: Mergent Bond Record (Utility Rates);
www.federalreserve.gov (Treasury Rates).

The data in Table 1 show that in August 2008 long-term triple-B utility interest rates were higher than at any time in the past two years. More important, recent market turbulence from the sub-prime lending crisis and recent bank failures, as well as concerns about renewed inflation have increased interest rates spreads (the differences between utility borrowing costs and U.S. Treasury interest rates) dramatically. While the Federal Reserve System has reduced short-term borrowing rates for banks (the Fed Funds rate) and the "flight to safety" experience has driven down some U.S. Treasury rates, corporate borrows have seen just the opposite trend. Increased risk aversion has caused significantly higher borrowing costs for corporations such as KCP&L. While the effects of market turbulence are not always well captured in financial models for estimating the rate of return, the evolving long-term borrowing cost relationships for corporate entities should be considered explicitly in estimates of the going cost of equity capital.

Q. What levels of interest rates are forecast for the coming year?

A. Both corporate and government interest rates are expected to rise further from present levels. Schedule SCH-3, page 3, provides Standard & Poor's most recent economic forecast from its *Trends & Projections* publication for August 2008. S&P forecasts resumed economic growth after the first quarter of 2009. For 2008, growth in real Gross Domestic Product (GDP) is projected at only 1.7 percent with nominal GDP (real GDP plus inflation) at 4.0 percent. For 2009, nominal GDP growth is projected at 3.1 percent. These projected growth rates compare to a real rate for 2007 of 2.0 percent and a nominal rate of 4.8 percent. S&P also forecasts that interest rates will

rise from current levels. The summary interest rate data are presented in the following table:

Table 2
Standard & Poor's Interest Rate Forecast

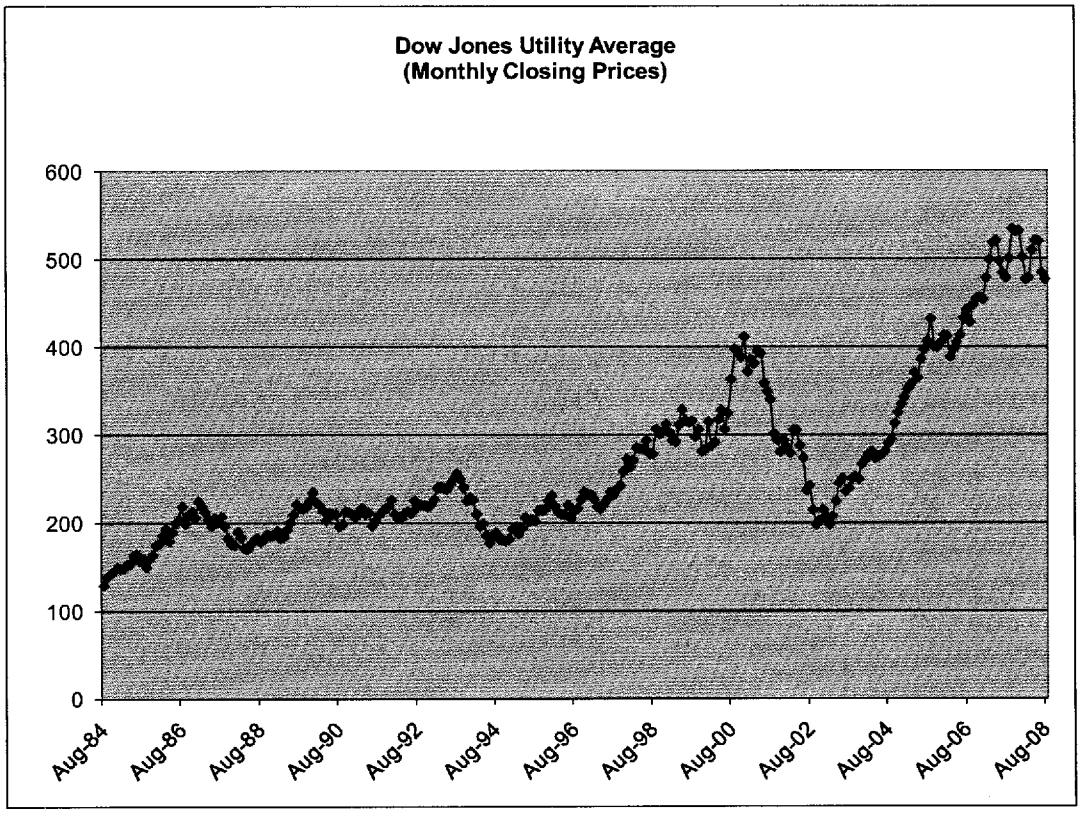
	August 2008 Average	Average 2008 Est.	Average 2009 Est.
Treasury Bills	1.7%	1.8%	2.4%
10-Yr. T-Bonds	3.9%	3.9%	4.5%
30-Yr. T-Bonds	4.5%	4.5%	4.9%
Aaa Corporate Bonds	5.6%	5.6%	6.1%

Sources: www.federalreserve.gov, (August 2008 Averages);
Standard & Poor's *Trends & Projections*, August 2008, page 8 (Projected Rates).

The data in Table 2 show that interest rates in 2009 are projected to increase from current levels. The average 30-year-term Treasury bond rate for 2009 is projected by S&P to reach 4.9 percent in this period, relative to the current level of 4.5. Similarly, the rate on corporate bonds is expected to increase from 5.6 percent to 6.1 percent, a rise of 50 basis points. These increasing interest rate trends offer important perspective for judging the cost of capital in the present case and illustrate why the return on equity must be set at a level sufficient to reflect these rising costs.

Q. How have utility stocks performed during the past several years?

A. Utility stock prices have fluctuated widely. The Dow Jones Utility Average (DJUA) has ranged between about 200 and 500 during the past six years. The wider fluctuations in more recent years are vividly illustrated in the following graph of DJUA prices over the past 25 years.



Widely fluctuating prices for natural gas as well as recent increases in coal prices and other uncertainties have created further unsettling conditions. These factors and continuing concerns for the more competitive market environment for all utility services will likely create further uncertainties and market volatility for utility shares. In this environment, investors' return expectations and requirements for providing capital to the utility industry remain high relative to the longer-term traditional view of the utility industry.

Q. What is the industry's current fundamental position?

A. Many electric utilities are attempting to return to their core businesses and hope to see more stable results over the next several years. S&P reflects this sentiment in its most recent *Electric Utility Industry Survey*:

Standard & Poor's Industry Surveys

> We expect the performance of both the electric utility sector and the individual companies within the sector to remain volatile over the next several years. However, we believe the stocks will be less volatile than they were in the first few years of the decade.... The performance of the sector, however, will remain sensitive to the macroeconomic environment and market forces surrounding it. (Standard & Poor's *Industry Surveys*, Electric Utilities, August 14, 2008, p. 4)

Value Line notes electric utilities' relatively poor performance this year:

Value Line Investors' Survey

> As a group, utility stocks have held up better than the overall market in recent weeks, but have performed just as poorly since the start of 2008. Many of these equities appear to be fully valued or even overvalued. (*Value Line Investment Survey*, Electric Utility (West) Industry, August 8, 2008, p. 1781.

Price volatility for utility shares and credit market gyrations make it all the more difficult to estimate the fair, on-going cost of capital.

Over the past several years, the greatest consideration for utility investors has been the industry's transition to competition. With the passage by Congress of the Energy Policy Act in 1992 and the Federal Energy Regulatory Commission's (FERC) Order 888 in 1996, the stage was set for vastly increased competition in the electric utility industry. The 1992 Act's mandate for open access to the transmission grid and FERC's implementation through Order 888, including subsequent orders such as Order 2000 and Order 890, effectively opened the market for wholesale electricity to competition. Previously protected utility service territory and lack of transmission access in some parts of the country had limited the availability of competitive bulk power prices. The Energy Policy Act and Order 888 have essentially eliminated such constraints for incremental power needs.

In addition to wholesale issues at the federal level, many states implemented retail access and have opened their retail markets to competition. Prior to the Western energy crisis of 2000-2001, investors' concerns had focused principally on appropriate transition mechanisms and the recovery of stranded costs. More recently, however, provisions for dealing with power cost adjustments have become a larger concern. The Western energy crisis refocused market concerns and contributed significantly to increased market risk perceptions for companies without power cost recovery provisions. As expected, the opening of previously protected utility markets to competition, and the uncertainty created by the removal of regulatory protection, has raised the level of uncertainty about investment returns across the entire industry.

Q. Is KCP&L affected by these same market uncertainties and increasing utility capital costs?

A. Yes. To some extent all electric utilities are being affected by the industry's transition to competition. KCP&L's power costs and other operating activities have been significantly affected by transition and restructuring events around the country. In fact, the uncertainty associated with the changes that are transforming the utility industry as a whole, as viewed from the perspective of the investor, remain a factor in assessing any utility's required ROE, including the ROE from KCP&L's operations in Missouri. For KCP&L specifically, its large construction program, its historical lack of a fuel adjustment clause, and its heavy dependence on wholesale transactions to avoid retail rate increases all increase the Company's risk profile. This is true even though Missouri has not adopted retail choice or other major forms of restructuring.

Q. What has been the effect on KCP&L of the acquisition of Aquila, Inc. by KCP&L's parent company Great Plains Energy Incorporated?

A. I have not been able to discern any negative effect. On July 14, 2008 Standard & Poor's Ratings Services affirmed the long-term ratings of KCP&L, including the BBB corporate credit rating, and raised its commercial paper credit rating from A-2 to A-3. On July 15, 2008 Moody's Investors Service affirmed the ratings of KCP&L.

Q. How do capital market concerns and financial risk perceptions affect the cost of equity capital?

A. As I discussed previously, equity investors respond to changing assessments of risk and financial prospects by changing the price they are willing to pay for a given security. When the risk perceptions increase or financial prospects decline, investors refuse to pay the previously existing market price for a company's securities and market supply and demand forces then establish a new lower price. The lower market price typically translates into a higher cost of capital through a higher dividend yield requirement, as well as the potential for increased capital gains if prospects improve. In addition to market losses for prior shareholders, the higher cost of capital is transmitted directly to the company by the need to issue more shares to raise any given amount of capital for future investment. The additional shares also impose additional future dividend requirements and reduce future earnings per share growth prospects.

Q. How have regulatory commissions responded to these changing market and industry conditions?

A. Over the past five years, allowed equity returns have generally followed the interest rate changes. The following table summarizes the overall average ROEs allowed for electric utilities since 2004:

Authorized Electric Utility Equity Returns

	2004	2005	2006	2007	2008
1st Quarter	11.00%	10.51%	10.38%	10.27%	10.50%
2nd Quarter	10.54%	10.05%	10.68%	10.27%	10.57%
3rd Quarter	10.33%	10.84%	10.06%	10.02%	
4th Quarter	10.91%	10.75%	10.39%	10.56%	
Full Year Average	10.75%	10.54%	10.36%	10.36%	10.53%
Average Utility Debt Cost	6.20%	5.67%	6.08%	6.11%	6.32%
Indicated Average Risk Premium	4.55%	4.87%	4.28%	4.25%	4.21%

Source: *Regulatory Focus*, Regulatory Research Associates, Inc., Major Rate Case Decisions, July 2, 2008.

The data above show that since 2004 equity risk premiums (the difference between allowed equity returns and utility interest rates) have ranged from 4.21 percent to 4.87 percent. At the low end of this risk premium range, with an allowed equity risk premium of 4.21 percent, the indicated cost of equity is 11.20 percent (6.99% projected triple-B interest rate + 4.21% risk premium = 11.20%)[1]. At the upper end of this risk premium range, with an allowed equity risk premium of 4.87 percent, the indicated cost of equity is 11.86 percent (6.99% projected triple-B interest rate + 4.87% risk premium = 11.86%). As I will demonstrate in the following section, my

[1] The triple-B utility interest rate of 6.99% is equal to the forecasted 30-year Treasury bond rate of 4.9% from Schedule SCH-3, page 3, plus the average triple-B utility spread over long-term Treasuries of 2.09% for the 12 months ended August 2008, as shown in Schedule SCH-3, page 2.

longer-term risk premium study, upon which I rely to test my DCF results, produces a slightly more conservative estimate of the required rate of return.

V. COST OF EQUITY CAPITAL FOR KCP&L

Q. What is the purpose of this section of your testimony?

A. Here I present my quantitative studies of the cost of equity capital for KCP&L and discuss the details and results of my analysis.

Q. How are your studies organized?

A. In the first part of my analysis, I apply three versions of the DCF model to a 30-company group of electric utilities based on the selection criteria discussed previously. In the second part of my analysis, I present my risk premium study and I review risk premium results from the longer-term Ibbotson Stocks, Bonds, Bills, and Inflation market data (Ibbotson data) now published by Morningstar, Inc.

My DCF analysis is based on three versions of the DCF model. In the first version of the DCF model, I use the constant growth format with long-term expected growth based on analysts' estimates of five-year utility earnings growth. While I continue to endorse a longer-term growth estimation approach based on growth in overall gross domestic product, I show the traditional DCF results because this is the approach that has traditionally been used by many regulators. In the second version of the DCF model, for the estimated growth rate, I use the estimated long-term GDP growth rate. In the third version of the DCF model, I use a two-stage growth approach, with stage one based on *Value Line*'s three-to-five-year dividend projections and stage two based on long-term projected growth in GDP. The dividend yields in all three of the annual models are from *Value Line's* projections of

dividends for the coming year and stock prices are from the three-month average for the months that correspond to the *Value Line* editions from which the underlying financial data are taken.

Q. Why do you believe the long-term GDP growth rate should be used to estimate long-term growth expectations in the DCF model?

A. Growth in nominal GDP (real GDP plus inflation) is the most general measure of economic growth in the U.S. economy. For long time periods, such as those used in the Ibbotson Associates rate of return data, GDP growth has averaged between 5 percent and 8 percent per year. From this observation, Professors Brigham and Houston offer the following observation concerning the appropriate long-term growth rate in the DCF Model:

> Expected growth rates vary somewhat among companies, but dividends for mature firms are often expected to grow in the future at about the same rate as nominal gross domestic product (real GDP plus inflation). On this basis, one might expect the dividend of an average, or "normal," company to grow at a rate of 5 to 8 percent a year. (Eugene F. Brigham and Joel F. Houston, *Fundamentals of Financial Management*, 11th Ed. 2007, page 298.)

Other academic research on corporate growth rates offers similar conclusions about GDP growth, as well as concerns about the long-term adequacy of analysts' forecasts:

> Our estimated median growth rate is reasonable when compared to the overall economy's growth rate. On average over the sample period, the median growth rate over 10 years for income before extraordinary items is about 10 percent for all firms. ... After deducting the dividend yield (the median yield is 2.5 percent per year), as well as inflation (which averages 4 percent per year over the sample period), the growth in real income before extraordinary items is roughly 3.5 percent per year. This is consistent with the historical growth rate in real gross domestic product, which has averaged about 3.4 percent per year over the period 1950-1998. (Louis K. C. Chan, Jason Karceski, and Josef Lakonishok, "The Level and Persistence of Growth Rates," The Journal of Finance, April 2003, p. 649)

> IBES long-term growth estimates are associated with realized growth in the immediate short-term future. Over long horizons, however, there is little forecastablility in earnings, and analysts' estimates tend to be overly optimistic. ... On the whole, the absence of predictability in growth fits in with the economic intuition that competitive pressures ultimately work to correct excessively high or excessively low profitability growth. (Ibid, page 683)

These findings support the notion that long-term growth expectations are more closely predicted by broader measures of economic growth than by near-term analysts' estimates. Especially for the very long-term growth rate requirements of the DCF model, the growth in nominal GDP should be considered an important input.

Q. How did you estimate the expected long-term GDP growth rate?

A. I developed my long-term GDP growth forecast from nominal GDP data contained in the St. Louis Federal Reserve Bank data base. That data for the period 1947 through 2007 is summarized in my Schedule SCH-4. As shown at the bottom of that schedule, the overall average for the period was 7.0 percent. The data also show, however, that in the more recent years since 1980, lower inflation has resulted in lower overall GDP growth. For this reason I gave more weight to the more recent years in my GDP forecast. This approach is consistent with the concept that more recent data should have a greater effect on expectations and with generally lower near- and intermediate-term growth rate forecasts that presently exist. Based on this approach, my overall forecast for long-term GDP growth is 50 basis points lower than the long-term average, at a level of 6.5 percent.

Q. Please summarize the results of your electric utility DCF analyses.

A. The DCF results for my comparable company group are presented in Schedule SCH-5. The traditional constant growth DCF model results, with the projected growth rate

based on analysts' forecasts, are shown in the first column on page 1 of that exhibit. That analysis indicates an ROE range of 11.1 percent to 11.2 percent. In the second column of page 1, I recalculate the constant growth results with long-term forecasted growth in GDP as the projected growth rate. That analysis indicates an ROE estimate of 11.0 percent. Finally, in the third column of page 1, I present the multistage DCF results. The multistage model indicates an ROE of 10.8 percent. Based on all three versions of the DCF model, my analysis supports a reasonable ROE range of 10.8 percent to 11.2 percent.

Q. What are the results of your risk premium studies?

A. The details and results of my risk premium studies are shown in my Schedule SCH-6. These studies and other risk premium data indicate an ROE range of 11.10 percent to 11.49 percent.

Q. How are your risk premium studies structured?

A. My risk premium studies are divided into two parts. First, I compare electric utility authorized ROEs for the period 1980-2007 to contemporaneous long-term utility bond interest rates. The differences between the average authorized ROEs and the average interest rate for the year is the indicated equity risk premium. I then add the indicated equity risk premium to the forecasted triple-B utility bond interest rate to estimate ROE. Because there is a strong inverse relationship between risk premiums and interest rates (when interest rates are high, risk premiums are low and vice versa), further analysis is required to estimate the current risk premium level.

The inverse relationship between risk premiums and interest rate levels is well documented in numerous, well-respected academic studies. These studies typically

use regression analysis or other statistical methods to predict or measure the risk premium relationship under varying interest rate conditions. On page 2 of Schedule SCH-6, I provide regression analyses of the allowed annual equity risk premiums relative to interest rate levels. The negative and statistically significant regression coefficients confirm the inverse relationship between risk premiums and interest rates. This means that when interest rates rise by one percentage point, the cost of equity increases, but by a smaller amount. Similarly, when interest rates decline by one percentage point, the cost of equity declines by less than one percentage point. I use this negative interest rate change coefficient in conjunction with current interest rates to establish the appropriate current equity risk premium.

Q. How do the results of your risk premium study compare to levels found in other published risk premium studies?

A. Based on my risk premium studies, I am conservatively recommending a lower risk premium than is often found in other published risk premium data. For example, the most widely followed risk premium data are provided in the Morningstar Ibbotson data studies. These data, for the period 1926-2007, indicate an arithmetic mean risk premium of 6.1 percent for common stocks versus long-term corporate bonds. Under the assumption of geometric mean compounding, the Ibbotson risk premium for common stocks versus corporate bonds is 4.5 percent. Based on the more conservative geometric mean risk premium, the Ibbotson data indicate a cost of equity of 11.49 percent (6.99% forecasted debt cost + 4.5% risk premium = 11.49%). Based on the arithmetic risk premium, the Ibbotson data indicate a cost of equity of over 13 percent (6.99% forecasted debt cost + 6.1% risk premium = 13.09%).

Although I do not use the Ibbotson data in my final ROE estimates, I do review the data for their perspective on the overall market cost of equity capital.

Q. Please summarize the results of your cost of equity analysis.

A. The following table summarizes my results:

Summary of Cost of Equity Estimates

DCF Analysis	Indicated Cost
Constant Growth (Analysts' Growth Rates)	11.1%-11.2%
Constant Growth (GDP Growth Rate)	11.0%
Multistage Growth Model	10.8%
Reasonable DCF Range	10.8%-11.2%
Risk Premium Analysis	**Indicated Cost**
Utility Debt + Risk Premium	
Risk Premium (6.99% + 4.11%)	11.10%
Ibbotson Risk Premium Analysis	
Risk Premium (6.99% + 4.5%)	11.49%
KCP&L Requested Cost of Equity Capital	10.75%

Q. How should these results be interpreted by the Commission in setting the fair cost of equity for KCP&L?

A. Higher analysts' growth rates and higher dividend yields have increased DCF model results along with increases in utility interest rates. The similarly higher results from the risk premium models also indicate the increasing trend reflected in the quantitative model results. These factors show that KCP&L's requested ROE is a conservative estimate of its market required rate of return. Additionally, use of a lower DCF range would fail to recognize the ongoing risks and uncertainties that exist in the electric utility industry as well as the company-specific risks and uncertainties that KCP&L is currently facing. All these factors show that the

Company's requested 10.75 percent ROE is a reasonable estimate of the fair cost of equity capital.

Q. Does this conclude your testimony?

A. Yes, it does.

BEFORE THE PUBLIC SERVICE COMMISSION
OF THE STATE OF MISSOURI

In the Matter of the Application of Kansas City Power & Light Company to Modify Its Tariff to Continue the Implementation of Its Regulatory Plan	)))	Case No. ER-2009-____

AFFIDAVIT OF SAMUEL C. HADAWAY

STATE OF TEXAS)
) **ss**
COUNTY OF TRAVIS)

Samuel C. Hadaway, being first duly sworn on his oath, states:

1. My name is Samuel C. Hadaway. I am employed by FINANCO, Inc. in Austin, Texas. I have been retained by Great Plains Energy, Inc., the parent company of Kansas City Power & Light Company, to serve as an expert witness to provide cost of capital testimony on behalf of Kansas City Power & Light Company.

2. Attached hereto and made a part hereof for all purposes is my Direct Testimony on behalf of Kansas City Power & Light Company consisting of thirty-six (36) pages, having been prepared in written form for introduction into evidence in the above-captioned docket.

3. I have knowledge of the matters set forth therein. I hereby swear and affirm that my answers contained in the attached testimony to the questions therein propounded, including any attachments thereto, are true and accurate to the best of my knowledge, information and belief.

Samuel C. Hadaway
Samuel C. Hadaway

Subscribed and sworn before me this 3rd day of September 2008.

Davina G. Davis
Notary Public

My commission expires: 7-21-2012

My Comm. Exp. 07-21-2012

SAMUEL C. HADAWAY

FINANCO, Inc.
Financial Analysis Consultants

3520 Executive Center Drive, Suite 124
Austin, Texas 78731
(512) 346-9317

SUMMARY OF QUALIFICATIONS

- Principal, Financial Analysis Consultants (FINANCO, Inc.).
- Ph.D. in Finance and Econometrics.
- Extensive expert witness testimony in court and before regulatory agencies.
- Management of professional research staff in academic and regulatory organizations.
- Professional presentations before executive development groups, the National Rate of Return Analysts' Forum, and the New York Society of Security Analysts.
- Financial Management Association, Vice President for Practitioner Services.

EDUCATION

The University of Texas at Austin **Ph.D., Finance and Econometrics** **January 1975**	Dissertation: *An Evaluation of the Original and Recent Variants of the Capital Asset Pricing Model.*
The University of Texas at Austin **MBA, Finance** **June 1973**	Thesis: *The Pricing of Risk on the New York Stock Exchange.*
Southern Methodist University **BA, Economics** **June 1969**	Honors program. Departmental distinction.

OTHER EXPERIENCE

University of Texas at Austin **Adjunct Associate Professor** **1985-1988, 2004-Present**	Corporate Financial Management, Investments, and Integrative Finance Cases.
Texas State University San Marcos **Associate Professor of Finance** **1983-1984, 2003-2004**	Graduate and undergraduate courses in Financial Management, Managerial Economics, and Investment Analysis.
Public Utility Commission of Texas **Chief Economist and Director of Economic Research Division** **August 1980-August 1983**	Lead financial witness. Supervised Commission staff in research and testimony on rate of return, financial condition, and economic analysis.
Assistant Professor of Finance **Texas Tech University** **July 1978-July 1980** **University of Alabama** **January 1975-June 1978**	Member of graduate faculty. Conducted Ph.D. seminars and directed doctoral dissertations in capital market theory. Served as consultant to industry, church and governmental organizations.

Testimony On Behalf Of Texas PUC Staff:

- Texland Electric Cooperative, Dkt. No. 3896, February 1983
- El Paso Electric Company, Dkt. No. 4620, September 1982.
- Southwestern Bell Telephone Company, Dkt. No. 4545, August 1982.
- Central Power and Light Company, Dkt. No. 4400, May 1982.
- Texas-New Mexico Power Company, Dkt. 4240, March 1982.
- Texas Power and Light Company, Dkt. No. 3780, May 1981.
- General Telephone Company of the Southwest, Dkt. No. 3690, April 1981.
- Mid-South Electric Cooperative, Dkt. No. 3656, March 1981.
- West Texas Utilities Company, Dkt. No. 3473, December 1980.
- Houston Lighting & Power Company, Dkt. No. 3320, September 1980.

ECONOMIC ANALYSIS AND TESTIMONY

Antitrust Litigation:

- Marginal Cost Analysis of Concrete Production/Predatory Pricing (Stiles)
- Analysis of Lost Business Opportunity due to denial of Waste Disposal Site Permit (Browning-Ferris Industries, Inc.).
- Analysis of Electric Power Transmission Costs in Purchased Power Dispute (City of College Station, Texas).

Contract Litigation:

- Analysis of Cogeneration Contract/Economic Viability Issues(Texas-New Mexico Power Company)
- Definition of Electric Sales/Franchise Fee Contract Dispute (Reliant Energy HL&P)
- Analysis of Purchased Power Agreement/Breach of Contract (Texas-New Mexico Power Company)
- Regulatory Commission Provisions in Franchise Fee Ordinance Dispute (Central Power & Light Company)
- Analysis of Economic Damages resulting from attempted Acquisition of Highway Construction Company (Dillingham Construction Corporation).
- Analysis of Economic Damages due to Contract Interference in Acquisition of Electric Utility Cooperative (PacifiCorp).
- Analysis of Economic Damages due to Patent Infringement of Boiler Cleaning Process (Dowell-Schlumberger/The Dow Chemical Company).

Lender Liability/Securities Litigation:

- ERISA Valuation of Retail Drug Store Chain (Sommers Drug Stores Company).
- Analysis of Lost Business Opportunities in Failed Businesses where Lenders Refused to Extend or Foreclosed Loans (FirstCity Bank Texas, McAllen State Bank, General Electric Credit Corporation).

- Usury and Punitive Damages Analysis based on Property Valuation in Failed Real Estate Venture (Tomen America, Inc.).

Personal Injury/Wrongful Death/Lost Earnings Capacity Litigation:

- Analysis of Lost Earnings Capacity and Punitive Damages due to Industrial Accident (Worsham, Forsythe and Wooldridge).
- Analysis of Lost Earnings Capacity due to Improper Termination (Lloyd Gosselink, Ryan & Fowler).
- Present Value Analysis of Lost Earnings and Future Medical Costs due to Medical Malpractice (Sierra Medical Center).

Product Warranty/Liability Litigation:

- Analysis of Lost Profits due to Equipment Failure in Cogeneration Facility (WF Energy/Travelers Insurance Company).
- Analysis of Economic Damages due to Grain Elevator Explosion (Degesch Chemical Company).
- Analysis of Economic Damages due to failure of Plastic Pipe Water Lines (Western Plastics, Inc.)
- Analysis of Rail Car Repair and Maintenance Costs in Product Warranty Dispute (Youngstown Steel Door Company).

Property Tax Litigation:

- Evaluation of Electric Utility Distribution System (Jasper-Newton Electric Cooperative).
- Evaluations of Electric Utility Generating Plants (West Texas Utilities Company).

Valuations of Closely Held Businesses in Litigation Support and Federal Estate Tax Planning.

Kansas City Power & Light Company
Discounted Cash Flow Analysis
Column Descriptions

Column 1: Three-month Average Price per Share (Jun 2008-Aug 2008)

Column 2: Estimated 2009 Dividends per Share from Value Line

Column 3: Column 2 Divided by Column 1

Column 4: "Est'd 05-07 to 11-13" Earnings Growth Reported by Value Line

Column 5: "Next 5 Years" Company Growth Estimate as Reported by Zacks.com

Column 6: "Next 5 Years (per annum) Growth Estimate Reported by Thomson Financial Network (at Yahoo Finance)

Column 7: Average of Columns 4-6

Column 8: Column 3 Plus Column 7

Column 9: See Column 1

Column 10: See Column 2

Column 11: Column 10 Divided by Column 9

Column 12: Average of GDP Growth During the Last 10 year, 20 year, 30 year, 40 year, 50 year, and 60 year growth periods. See Schedule SCH-4

Column 13: Column 11 Plus Column 12

Column 14: See Column 2

Column 15: Estimated 2012 Dividends per Share from Value Line

Column 16: (Column 15 Minus Column 14) Divided by Three

Column 17: See Column 1

Column 18: See Column 14

Column 19: Column 18 Plus Column 16

Column 20: Column 19 Plus Column 19

Column 21: Column 20 Plus Column 16

Column 22: Column 21 Increased by the Growth Rate Shown in Column 23

Column 23: See Column 12

Column 24: The Internal Rate of Return of the Cash Flows in Columns 17-22 along with the Dividends for the Years 6-150 Implied by the Growth Rates shown in Column 23
