DIRECT TESTIMONY

OF

LARRY W. LOOS

Case No. ER-2009-____

QUALIFICATIONS

1 Q. PLEASE STATE YOUR NAME AND BUSINESS ADDRESS.

- 2 A. Larry W. Loos, 11401 Lamar, Overland Park, KS 66211.
- 3 Q. WHAT IS YOUR OCCUPATION?
- 4 A. I am an engineer and consultant employed by Black & Veatch Corporation (Black &
- 5 Veatch). I currently serve as a Director in Black & Veatch's Enterprise Management
 6 Solutions Division.
- 7 Q. HOW LONG HAVE YOU BEEN WITH BLACK & VEATCH?
- 8 A. Black & Veatch has employed me continuously since 1971.

9 Q. WHAT IS YOUR EDUCATIONAL BACKGROUND?

- 10 A. I am a graduate of the University of Missouri at Columbia, with a Bachelor of Science
- 11 Degree in Mechanical Engineering and a Masters Degree in Business Administration.

1 Q. ARE YOU A REGISTERED PROFESSIONAL ENGINEER?

- A. Yes, I am a registered Professional Engineer in the state of Missouri, as well as the states
 of Iowa, Colorado, Indiana, Kansas, Louisiana, Nebraska, and Utah.
- 4

Q. TO WHAT PROFESSIONAL ORGANIZATIONS DO YOU BELONG?

A. I am a member of the American Society of Mechanical Engineers, the National Society
of Professional Engineers, the Missouri Society of Professional Engineers, and the
Society of Depreciation Professionals.

8 Q. WHAT IS YOUR PROFESSIONAL EXPERIENCE?

9 A. I have been responsible for numerous engagements involving electric, gas, and other
10 utility services. Clients served include both investor-owned and publicly owned utilities;
11 customers of such utilities; and regulatory agencies. During the course of these
12 engagements, I have been responsible for the preparation and presentation of studies
13 involving cost classification, cost allocation, cost of service, allocation, rate design,
14 pricing, financial feasibility, weather normalization, normal degree-days, cost of capital,
15 valuation, depreciation, and other engineering, economic and management matters.

16 Q. PLEASE DESCRIBE BLACK & VEATCH.

A. Black & Veatch has provided comprehensive construction, engineering, consulting, and
management services to utility, industrial, and governmental clients since 1915. We
specialize in engineering and construction associated with utility services including
electric, gas, water, wastewater, telecommunications, and waste disposal. Service
engagements consist principally of investigations and reports, design and construction,
feasibility analyses, cost studies, rate and financial reports, valuation and depreciation

studies, reports on operations, management studies, and general consulting services.
 Present engagements include work throughout the United States and numerous foreign
 countries. Including professionals assigned to affiliated companies, Black & Veatch
 currently employs approximately 10,000 people.

5

Q. HAVE YOU PREVIOUSLY APPEARED AS AN EXPERT WITNESS?

6 A. Yes, I have. I have presented expert witness testimony before the Missouri Public 7 Service Commission (the "Commission") on several of occasions. I have also testified 8 before the Federal Energy Regulatory Commission ("FERC") and regulatory bodies in 9 the states of Colorado, Illinois, Indiana, Iowa, Kansas, Minnesota, New Mexico, New 10 York, Pennsylvania, North Carolina, South Carolina, Texas, Utah, and Vermont. I have 11 also presented expert witness testimony before District Courts in Iowa, Colorado, Kansas, 12 and Nebraska; and before the Courts of Condemnation in Iowa and Nebraska. I have also 13 served as a special advisor to the Connecticut Department of Public Utility Control.

INTRODUCTION

14 Q. FOR WHOM ARE YOU TESTIFYING IN THIS MATTER?

A. I am testifying on behalf of Kansas City Power & Light Company ("KCP&L" or
"Company").

17 Q. WHAT IS THE PURPOSE OF YOUR DIRECT TESTIMONY?

18 A. KCP&L asked me to recommend the most appropriate basis for functionally classifying
 19 and allocating production and transmission related costs between jurisdictions (Missouri,

1	Kansas, and FERC). In this regard, KCP&L requested that I focus on the allocation of
2	fixed production and transmission costs, margin associated with off-system sales, and
3	environmental control costs.

4 Q. IN KCP&L'S PRIOR RATE CASE, HOW WERE PRODUCTION AND 5 TRANSMISSION FIXED COSTS ALLOCATED?

6 A. In KCP&L's most recent rate case (Case No. ER-2007-0291), the Company and the 7 Commission Staff continued to allocate fixed production and transmission cost based on the average of the four-summer month's coincident peak demands ("4CP"). This is 8 9 different from the twelve coincident peak ("12CP") allocation basis that I understand 10 underlies the settlement approved by the Kansas Corporation Commission in KCP&L's 11 most recent rate case filed in Kansas (Docket No.07-KCPE-905-RTS). In its 2006 12 Missouri case (Docket No. ER-2006-0314), KCP&L requested, but the Commission did 13 not approve, using a 12CP allocator. Instead, the Commission adopted a 4CP allocation 14 of production and transmission fixed (capacity) cost.

Q. IN KCP&L'S PRIOR RATE CASE, HOW WAS MARGIN ASSOCIATED WITH OFF-SYSTEM SALES ALLOCATED?

A. In KCP&L's prior Missouri rate case (Case No ER-2006-0314), the Company proposed
to allocate margin associated with off-system sales on "unused energy." I understand this
allocation basis underlies the settlement approved by the Kansas Commission in
KCP&L's most recent rate case filed in Kansas. Again, in its 2006 Missouri case, the
Commission did not adopt KCP&L's proposal. Instead, the Commission adopted an
allocation based on energy deliveries. In KCP&L's most recent Missouri rate case,

Docket No ER-2007-0291, the Company allocated off-system sales margin based on
 energy deliveries.

3 Q. IN KCP&L'S PRIOR RATE CASES, HOW WERE COSTS ASSOCIATED WITH 4 ENVIRONMENTAL CONTROL ALLOCATED?

5 A. Based on my reading of the Commission's order in the Company's prior cases, the 6 allocation of pollution control related costs was not an issue. Examination of the 7 Company's jurisdictional cost study shows that the Company classified the fixed capital 8 and operating costs associated with pollution control equipment as capacity related. The 9 Company classified variable operating costs associated with commodities (consumables 10 such as limestone) used in pollution control equipment, the cost of purchasing 11 allowances, and the revenues realized from the sale of allowances as energy related. As I 12 previously discussed, the Commission ordered a 4CP allocator for allocating capacity 13 related costs and energy deliveries (adjusted for losses) for allocating energy related 14 costs.

Q. DOES USE OF DIFFERENT ALLOCATION BASES BY THE MISSOURI AND KANSAS COMMISSIONS TO ALLOCATE COSTS BETWEEN JURISDICTIONS RESULT IN ANY PROBLEM?

A. Yes, it does. For multi-jurisdictional utilities, the use of different jurisdictional allocation
bases usually results in the Company either not recovering its entire revenue requirement
or over recovering its revenue requirement. This result (over or under recovery) is
determined through the consequences of the actions of the Commissions. For KCP&L,
the different allocations used by the Missouri and Kansas Commissions results in
KCP&L not recovering its entire revenue requirement.

1	The Missouri jurisdiction operates at a somewhat higher load factor than the other
2	jurisdictions (Kansas and FERC). A 4CP capacity (demand) allocator will nearly always
3	allocate less cost to the higher load factor jurisdiction than use of a 12CP allocator.
4	Based on the Company's revenue requirement in this case, the use of a 4CP allocator will
5	result in an allocation to the Missouri jurisdiction of about \$1.7 million less than use of a
6	12CP allocator ¹ . Conversely, the use of a 12CP allocator will result in an allocation to
7	the Kansas and FERC jurisdictions of about \$1.7 million less than use of a 4CP allocator.
8	Thus, the use of different allocation bases results in the Company failing to recover
9	approximately \$1.7 million of its total revenue requirement. This under recovery results
10	in the Company actually earning (all other factors being equal) less than the authorized
11	return on equity.
12	Likewise, allocating the margin associated with off-system sales on an energy basis,
13	as the Missouri Commission has previously required, will result in a lower overall level

of cost allocated to the higher load factor jurisdiction than the use of an "unused energy"
allocator². These different allocation bases result in KCP&L returning approximately
104 percent of its off-system sales margin to customers in Kansas and Missouri. This
amounts to an approximate \$4 million under recovery by the Company in the current rate

18

case.

¹ Assuming the credit for off-system sales is allocated based on energy.

² The allocation of off-system sales based on energy will result in a higher level of offsystem sales allocated to the higher load factor jurisdiction (Missouri). Since these offsystem sales are credited to cost of service the overall level of cost allocated to the jurisdiction is reduced.

1Q.IN PRIOR RESPONSES, YOU REFER TO "FIXED" COSTS AND TO2"DEMAND" COSTS. IS THERE A DIFFERENCE?

A. Yes, there is. "Fixed" costs represent costs that do not tend to vary because of changes in
sales levels. For the most part, I consider electric utility costs, fixed, except for fuel, fuel
related costs, purchased power energy charges, and some consumables used in
environmental control equipment. I define demand (or capacity) related costs to be those
costs (predominantly fixed) which by their nature are related to, and are appropriately
allocated based on, customers' maximum loads.

9 Variable costs on the other hand are those costs that I do not consider fixed. Variable 10 costs tend to vary in response to changes in sales. I define energy related costs as those 11 costs (whether fixed or variable) which by their nature are related to, and are 12 appropriately allocated based on sales.

Q. IN YOUR PRIOR RESPONSE, YOU REFER TO ALTERNATIVE ALLOCATION AND CLASSIFICATION BASES. WHAT DO YOU MEAN BY CLASSIFICATION?

A. Jurisdictional allocations involve a three-step process even though many practitioners only show one. The first step is the functionalization of cost based on the nature of the cost. The functions typically used in jurisdictional cost allocations include categories such as production (power supply), transmission, and directly assigned. These broad functions may be further separated into "sub-functional" components such as base, intermediate, and peaking resources. 1 The second step involves the classification of functional costs into capacity, energy, 2 customer, and other costs. These functionally classified costs correspond to the basic 3 allocation factors used to allocate cost.

The final step is the application of appropriate capacity, energy, customer, or other allocation factors to the functionally classified costs. Many applications collapse this three-step process into just one-step, by allocating costs associated with individual accounts on some basis. This one-step process usually works reasonably well. However, when a plant or operation and maintenance expense account includes costs associated with more than one function or classification, this one-step process can become somewhat cumbersome.

11 Q. HOW DO YOU ORGANIZE THE BALANCE OF YOUR DIRECT TESTIMONY?

A. I will first outline considerations and criteria, which I believe one should objectively use
to evaluate the reasonableness and equity of alternative allocation and classification
bases. Based on these considerations and criteria, I will then evaluate the merits of a
number of allocation bases for allocating and/or classifying:

- 16 1) Margin associated with off-system sales
- 17 2) Steam plant environmental control equipment costs
- 18 3) Steam plant boiler maintenance
- 19 4) Capacity related power supply costs
- 20 5) Transmission system costs
- I conclude my prepared direct testimony with recommendations for allocating costs to
 jurisdictions in this case.

8

1

Q. DO YOU SPONSOR ANY SCHEDULES?

2 A. Yes, I do. I sponsor the following Schedules:

3	•	Schedule LWL-1 – Generating Station Cost Characteristics – Example
4	•	Schedule LWL-2 – Characteristics of KCP&L Generating Stations
5	•	Schedule LWL-3 – KCP&L Smoothed 2007 Hourly Load Curve
6	•	Schedule LWL-4 – Power Supply Revenue Requirements - Summary
7	•	Schedule LWL-5 – Impact of Properly Classifying and Allocating Off-System
8		Sales
9	•	Schedule LWL-6 – Impact of Properly Classifying and Allocating Off-System
10		Sales and Environmental Costs
11	•	Schedule LWL-7 – Impact of Properly Classifying and Allocating Off-System
12		Sales, Environmental Costs, and Boiler Maintenance
13	•	Schedule LWL-8 – Impact of Single CP and 12CP Allocation of Power Supply
14		Capacity Related Costs
15	•	Schedule LWL-9 – Allocation Results - Capital Substitution Method
16	•	Schedule LWL-10 – Allocation Results - Base, Intermediate, Peaking Method
17	•	Schedule LWL-11 – Allocation Results - Economic Rents Allocation Method
18	•	Schedule LWL-12 – Allocation Results - Hour-by-Hour Allocation Method
19	•	Schedule LWL-13 – Summary of Allocation Results

1 Q. DO YOU SPONSOR THE JURISDICTIONAL ALLOCATION PROPOSED BY 2 THE COMPANY IN THIS CASE?

3 A. No, I do not. My testimony is limited to the reasonableness of alternative allocation (and 4 classification and functionalization) bases. Based on the considerations I outline, I 5 recommend the bases to functionally classify and allocate costs in this case. Company 6 witness John P. Weisensee uses the bases I recommend to allocate costs to jurisdictions 7 in this case.

8

Q. WHAT RECOMMENDATIONS DID YOU PROVIDE MR. WEISENSEE?

- 9 A. I recommend the following:
- 10 1) Classify and allocate the margin associated with off-system sales on the same 11 basis as the fixed costs of the generating stations used to generate the energy used 12 to make those sales;
- 13 2) Classify the fixed and operating costs associated with steam plant environmental 14 control equipment as energy and allocate accordingly;
- 15 3) Classify the non-labor cost of steam plant boiler maintenance expense as energy 16 and allocate accordingly;
- 17 4) Allocate capacity related power supply costs based on each jurisdiction's 18 contribution to the system peak demands during the four summer months, that is, 19 on a 4CP basis; and
- 20 5) Classify and allocate transmission cost based on the classification and allocation 21 of power supply fixed cost.

CONSIDERATIONS AND CRITERIA

1	Q.	WHA	AT CRITERIA DO YOU USE TO EVALUATE THE REASONABLENESS OF
2		JURI	SDICTIONAL ALLOCATIONS?
3	A.	The c	riteria that I use include:
4		1)	Taken as a whole, is the resulting allocation fair?
5		2)	Does the allocation approach reasonably consider the "cost drivers" associated
6			with the specific items allocated?
7		3)	Does the allocation treat various cost elements consistently?
8		4)	Does the allocation unreasonably affect or unjustly "enrich" one or more
9			jurisdictions or the utility?
10		5)	Are the data required to develop the allocation reasonably available?
11		6)	Will the allocation basis produce relatively stable results from one period to the
12			next?
13		7)	Are the results unduly disruptive?
14	Q.	ном	V DO YOU EVALUATE THE FAIRNESS OF AN ALLOCATION?
15	A.	Gene	rally, most people consider an allocation that recognizes both the nature of costs and
16		the co	ost drivers to be fair. I generally agree, provided the nature of the cost and the cost
17		drive	rs are indeed <u>fully recognized</u> .
18		R	egardless of the nature of costs and cost drivers, an allocation that does not permit
19		the ut	ility a reasonable opportunity to earn its allowed rate of return, I believe is patently
20		unfai	r. KCP&L currently finds itself in this situation.

1Q.ARE THERE CERTAIN COSTS THAT THE MISSOURI COMMISSION2ALLOWS KCP&L TO RECOVER THAT OTHER JURISDICTIONS DO NOT?

3 A. Yes, there are. There are also costs other jurisdictions allow that the Missouri 4 Commission does not.

5 The fact that one commission may deny recovery of a specific cost is not the issue I 6 address. The issue I address is the opportunity for the Company to recover fully all of the 7 costs for which the jurisdiction does permit recovery. The true test of this issue is 8 whether the sum of the allocation factors used by the various jurisdictions to allocate a 9 cost (recoverable by all jurisdictions) equals 100%.

10Q.DO YOU BELIEVE THAT BECAUSE KANSAS USES A 12CP ALLOCATION11BASIS, THE MISSOURI COMMISSION SHOULD ADOPT A 12CP12ALLOCATION IN THE INTEREST OF KEEPING THE COMPANY WHOLE?

A. No, I do not. Nor do I expect the Kansas Commission to adopt a 4CP allocation basis solely to keep the Company whole.

I do believe, however, that when either Commission (Missouri or Kansas) evaluates allocation alternatives, one consideration should be whether using that allocation allows (or increases the probability that) the Company to recover all of its costs. After all, whether it is Kansas or Missouri making the allocation it is the same total pool of cost. The allocation of that pool of cost needs to be allocated so the Company recovers 100 percent of it.

1 Q. YOU REFER TO "COST DRIVERS." WHAT DO YOU MEAN BY THIS TERM?

A. "Cost drivers" represent those factors which tend to influence cost levels. For example,
sales of energy drive fuel costs. As sales increase, fuel costs increase. However, fuel
costs also depend on the mix of the generating units used (the cost drivers) to generate
energy. This mix generally relates to overall load levels, time of day, season, availability
of generating units, etc.

7 Q. WHAT COST DRIVERS SHOULD THE COMMISSION CONSIDER IN 8 EVALUATING ALTERNATIVE ALLOCATION BASES?

9 A. Many costs are dependent on multiple factors. A classic example is in the natural gas
pipeline industry, where historically the FERC recognized that "pipelines are built to
supply service not only on the few peak days but on all days throughout the year. In
proving the economic feasibility of the project in certificate proceedings, reliance is
placed upon the annual as well as the peak deliveries."³ FERC continues to recognize
distance of haul, as well as capacity considerations in setting pipeline rates.

15 In the electric industry, one generally considers that transmission system costs are 16 dependent on the capability (capacity) of the transmission system to move power. As a 17 result, normally, transmission system costs are classified as capacity and are allocated on 18 some basis solely related to the maximum system demand⁴.

³ Consolidated Gas Supply Corp. v. FPC, 520 F.2d 1176

⁴ Unless otherwise specified, my use of the term maximum system demand includes any allocation basis that reflects coincidental peak demands, whether single coincident peak (1CP), 4CP, or 12CP. Likewise, unless otherwise specified, my reference to coincidental peak allocation bases refers to 1CP, 4CP, and 12CP allocators.

Q. DOES USE OF A CP-BASED ALLOCATOR RECOGNIZE TRANSMISSION SYSTEM "COST DRIVERS"?

3 Yes, in large part. The size of the conductor, capacity of substations, equipment ratings, A. 4 and other elements that contribute to costs are designed in consideration of the capacity 5 necessary to meet maximum load requirements placed on those elements to move power 6 and energy. However, to some extent, capacity requirements depend on the "foot-print" 7 of the transmission system. As the "foot-print" increases, costs increase because of the 8 additional distances (length of conductor and associated line losses) that are required to 9 interconnect the system. Thus, transmission system costs depend in part on the proximity 10 of generating stations and interconnections to load centers.

11 With regard to electric generating facilities, the classification of 100 percent of fixed 12 power supply costs to capacity and allocation on the basis of coincidental peak allocators 13 (whether 1CP, 4CP, or 12CP), is based on the assumption that the sole determinant of the 14 fixed costs of electric generation is the capacity of the generating stations used to serve 15 customers. This fails to recognize other cost drivers. Electric utilities, such as KCP&L, 16 require a mix of generating resources to meet customers' power and energy requirements 17 economically and reliably. KCP&L's mix includes nuclear, coal-fired steam, wind, and 18 combustion turbine (combined-cycle and simple-cycle) based generating resources. Each 19 type of generating station has different fixed and variable cost characteristics. The 20 different fixed and variable cost characteristics allow electric utilities to manage cost 21 while meeting customers' requirements. The capacity to meet customers' maximum 22 demands (plus allowance for reserves) drives (determines) the combined capacity of all 23 power supply resources (generation and purchases) needed. The mix of generating

station capacity depends not on the total capacity required but how most economically to
 meet customers' annual energy requirements.

3 Q. CAN YOU DEMONSTRATE HOW AN ELECTRIC UTILITY CAN MINIMIZE 4 COSTS THROUGH THE MIX OF GENERATING STATION CAPACITY 5 WHILE MEETING SYSTEM CAPACITY AND ENERGY REQUIREMENTS?

A. Yes, I can, through use of a simplified example. I show this example in Schedule LWLIn Schedule LWL-1, I assume in my example that there are two types of generating
equipment available. One is a base load resource, such as a large coal-fired steam
generating station. The other is a peaking resource, such as a simple cycle combustion
turbine-generating unit.

In Schedule LWL-1, I assume that construction costs for base load and peaking resources amount to \$1,500 and \$500 per kW installed, respectively (Line 2). I have further assumed that variable costs amount to \$0.015 and \$0.120 per kWh, respectively (Line 5).

15 To calculate annual fixed cost (Line 4), I apply an "all-in fixed charge rate" (Line 3) 16 to the capital cost associated with each type of generating resource. This all-in fixed 17 charge rate includes allowance for all fixed costs including depreciation, return, taxes, 18 and fixed operation and maintenance expenses. I use a higher fixed charge rate for the 19 base load resource to recognize the higher fixed operating costs relative to a peaking 20 resource (simple cycle CT). As I show on Line 4 of Sheet 1, given these assumptions, the 21 annual fixed costs associated with the base load resource is \$300 per kW-year. The 22 annual fixed cost for the peaking resource is \$90 per kW-year.

I then calculate the total annual cost at various assumed capacity factors. Based on
 the estimated cost levels I use, I show in Sheet 1 (Lines 6 through 17) annual cost per kW
 of capacity at various capacity factors. On Lines 18 through 29, I show the annual cost
 per kWh. I plot these values in the graphs I show to the right of the tabular data.

5

Q.

WHAT DO THESE GRAPHS SHOW?

A. The upper graph shows the total annual cost per kW (Y-axis) at various capacity factors
(X-axis) for both the base load and peaking resource. The lower graph shows the annual
cost per kWh. In both curves, I show (based on my assumed cost levels) that when
operating at capacity factors <u>lower</u> than about 25% (2,000 hours) the peaking unit
represents the least cost resource. Conversely, so long as the unit operates at a capacity
factor higher than about 25%, the base load resource represents the least cost option.

12

Q.

HOW DO YOU MINIMIZE COST UNDER YOUR EXAMPLE?

13 A. In Schedule LWL-1, Sheet 2, I show a simplified illustrative load duration curve. A load 14 duration curve represents the number of hours (X-axis) that load equals or exceeds a specific level (Y-axis), over a specified period (typically one-year). In my previous 15 16 example, I found that the peaking plant operated at less than 2,000 hours is more 17 economical than the base load plant operated at less than 2,000 hours. My illustrative 18 load duration curve shows that the load exceeds 3,000 MW, 2,000 hours during the year. 19 Therefore, I minimize cost with 3,000 MW of base load capacity and 2,000 MW of 20 peaking capacity. Based on my assumed cost levels, total plant costs in my example 21 would amount to \$5.5 billion (\$1,500/kW * 3,000,000 kW + \$500/kW * 2,000,000 kW) 22 and total annual fixed and variable cost would amount to \$1.6 billion.

1 Q. CAN YOU DEMONSTRATE THAT THIS MIX REPRESENTS THE MINIMUM 2 COST?

3 A. Yes, I can. In Schedule LWL-1, Sheet 3, I show construction cost and annual costs (fixed 4 and variable) to serve a 5,000 MW system peak. In my example, I assume 2,500, 3,000, 5 and 3,500 MW of base load resources and 2,500, 2,000, and 1,500 MW of peaking 6 resources. In each of these three scenarios total capacity amounts to 5,000 MW. As I 7 show in Sheet 3, Line 12, total annual costs amount to \$1.638 billion when 3,000 MW of 8 base load and 2,000 MW of peaking resources are used. This annual cost increases by 9 about 1 percent to \$1.651 billion if 3,500 MW of base load and 1,500 MW of peaking 10 resources are used (Scenario 2, Lines 14 through 21). If 2,500 MW each of base load and 11 peaking capacity are used, the annual cost in my example increases by about 4 percent to 12 \$1.697 billion (Scenario 3, Lines 22 through 29).

13 Q. DOES YOUR EXAMPLE RECOGNIZE REAL WORLD CONSIDERATIONS?

A. Yes, it does. Admittedly, I use a simple example whereas actual conditions include a
 number of complicating factors I did not attempt to model. Some of these complicating
 factors include:

- 17 **1)** Reserve requirements;
- 18 2) Implications of existing resources (sunk costs);
- 19 3) Implications of adding resources in "lumps;"
- 20 4) Inability to exactly match the capacity required with installed capacity;
- 21 5) Uncertainty associated with actual construction and operating costs; and
- 22 6) Uncertainly associated with future load (annual and peak) growth.

1	Though my simple example does not capture all the dynamics of power supply
2	planning, it does capture the implications of the fundamental trade off in costs between
3	base load and peaking resources.

4 Q. WHAT CONCLUSIONS DO YOU REACH BASED ON THE EXAMPLE YOU 5 SHOW IN SCHEDULE LWL-1?

A. With regard to the economic selection of generating resources, both system maximum
demand <u>and</u> capacity factor are cost drivers. Coincident peak demand drives the total
capacity required (in my simplified example, 5,000 MW) regardless of the cost
characteristics of the generating resources. Capacity factor drives the mix of generating
resources (in my example, 3,000 MW of base and 2,000 MW of peaking) which will
minimize total cost by:

- Trading off higher fixed cost against lower variable cost for generating resources
 operated at high capacity factor, and
- 14 2) Trading off lower fixed cost against higher variable cost for generating resources
 15 operated at lower capacity factor.

16 Q. WHAT DO YOU MEAN BY INTERNALLY CONSISTENT ALLOCATIONS?

17 A. Very simply, interrelated costs must be allocated on a consistent basis. I will address this
18 concept more fully in connection with my discussion of the classification of off-system
19 sales margins.

1Q.HOW CAN AN ALLOCATION UNREASONABLY "ENRICH" ONE2JURISDICTION?

A. This represents an element of fairness. Jurisdiction A is unjustly enriched when costs
 reasonably associated with serving that jurisdiction (say for example, Missouri) are
 assigned through the allocation process to Jurisdiction B (say for example, Kansas). This
 approach results in either Jurisdiction B or the Company subsidizing Jurisdiction A.

Q. WHY IS THE AVAILABILITY OF DATA A CONSIDERATION IN THE 8 EVALUATION OF ALTERNATIVE ALLOCATION BASES?

9 A. The ability to allocate costs fairly and accurately requires reliable data. When data are
10 not available, reasonable results can sometimes be achieved through synthesis. More
11 often, the allocation needs to be modified to accommodate data limitations.

On the other hand, the fact that data reliable or accurate to the fifth decimal point may not be available is no reason to abandon an allocation approach. When reasonable unbiased estimates can be made upon which to develop relative relationships, those estimates should be relied upon. In many instances, relative relationships are known, but cannot be measured absolutely. I believe that it is much more important to recognize and accommodate known relationships than it is to measure these relationships to the nearest penny.

A case in point is the simple example I present in Schedule LWL-1. Whether the cost of base load generation is \$1,500 per kW, \$1,250 per kW, or \$2,000 per kW does not affect the conclusion reached. We may not know exactly what base load or peaking resources cost; however, we do know that the capital cost of base load resources

19

1

2

substantially exceeds the capital cost of peaking resources, and that the variable cost of peaking resources substantially exceeds the variable cost of base load resources.

3 Q. WHY DO YOU CONSIDER IT IMPORTANT THAT THE ALLOCATION 4 PRODUCE RELATIVELY STABLE RESULTS?

A. Once an allocation basis is established and adopted by all jurisdictions that method
should continue to be applied until circumstances change. Allocations that produce
substantially different results from year to year may result in substantial shifts in costs
that are unduly disruptive and inherently inequitable to customers and the Company.
Further, changes in jurisdictional allocation bases should not be unduly disruptive to
customers in any jurisdiction.

KCP&L POWER SUPPLY

11 Q. DO YOU USE ACTUAL COMPANY COST LEVELS TO EVALUATE THE 12 IMPLICATIONS OF THE ALTERNATIVES YOU EVALUATE?

A. Yes, I do. Based on the Company's 2007 operating results including a 10.75 percent
 return on equity, I developed the total revenue requirement associated with the
 Company's power supply and transmission functions. I further separated this total
 revenue requirement into nuclear, steam, wind, other generation, purchased power, and
 off-system sales sub functions.

Q. DOES THE ADDITION OF GENERATING RESOURCES OVER TIME AFFECT THE ECONOMICS OF POWER SUPPLY?

A. Yes, it does. The ultimate mix of resources reflects the evolution of KCP&L's growth in
load and generation. As KCP&L added resources, the economics, load, forecast load
growth, and other factors at the time of planning for an addition controlled the decision of
the size and kind of generation asset KCP&L should add at each point in time.

7 Q. HAVE YOU PREPARED A SCHEDULE THAT SHOWS SOME OF THESE 8 DIFFERENT CHARACTERISTICS?

9 A. Yes, I have. In Schedule LWL-2, Sheet 1 I show data related to each of KCP&L's
10 generating resources that I obtained from KCP&L's 2007 FERC Form 1.

11 Q. DO YOU HAVE ANY OBSERVATIONS BASED ON EXAMINATION OF THE 12 INFORMATION YOU SHOW IN SCHEDULE LWL-2, SHEET 1?

- 13 A. Yes, I do. I identified several anomalies. These are:
- 141)For the most part, the original cost per kW (Line 20) of the Wolf Creek Nuclear15Station and the Spearville Wind Farm are more than 3 times the original cost (per16kW) of the other generating resources. I expect this high original cost because of17the technologies involved and the recent construction of the Spearville facility.
- 182)The variable cost for Wolf Creek (0.45 cents per kWh) and Spearville (zero) are19less than ½ the lowest variable cost (Iatan, \$0.96 cents per kWh) of the other20plants.

1		3)	Because of the explosion and rebuild of the Hawthorn 5 unit, the original cost
2			associated with this unit is considerably in excess of what I would expect given its
3			date of initial installation and the original cost of the other steam plants.
4		4)	The variable cost at Montrose is somewhat higher than what I would expect in
5			light of the variable costs reported for the other steam plants.
6		In	Schedule LWL-2, Sheet 2 I have prepared a graph that shows on a relative basis:
7		1)	The original cost per kW of capacity;
8		2)	The variable cost per kWh actually generated; and
9		3)	The capacity factor for each station.
10		In	order to place values into perspective, and manage scale, I show the values for
11		each p	plant relative to the KCP&L average. For example, the fuel cost at Iatan amounts to
12		0.96 c	cents per kWh (Schedule LWL-2, Sheet 1, Line 28, Column E), whereas the system
13		averag	ge fuel cost amounts to 1.19 cents per kWh (Line 28, Column P). Thus, Iatan's fuel
14		cost a	mounts to 81 percent of the system average ($0.96 / 1.19 = 81\%$). This 81 percent
15		value	is what I show in Schedule LWL-2, Sheet 2.
16	Q.	BASE	ED ON EXAMINATION OF SHEETS 1 AND 2 OF SCHEDULE LWL-2,
17		WHA	T CONCLUSIONS DO YOU REACH?
18	A.	As I i	ndicated above, there are some dislocations in the information set forth in Sheets 1
19		and 2	. In order to eliminate the implications of these dislocations, for the purpose of my
20		comp	arisons:

21 1) I eliminate Wolf Creek and Spearville from the comparison;

- I restate the original cost of the Hawthorn 5 unit to the estimated original cost
 balance prior to the explosion and rebuild in 2001; and
 As with Hawthorn 5, I restate the original cost at Montrose to the estimated
 original cost in 1998 in recognition of the age of the plant and the implication of
 interim replacements and additions when developing trended costs based on date
 of initial construction.
- In Sheet 4, I plot the values I show in Sheet 3, in the same fashion as in Sheet 2 for
 Sheet 1. In addition, in Sheet 4, I added trended costs per kW to the graph.
- 9

Q. WHAT IS THE PURPOSE OF TRENDING THE COST LEVELS?

10 A. I trend all costs to 2007 levels in order to eliminate the implications of inflation when 11 comparing unit costs. By doing so, I eliminate from my comparison differences in 12 construction costs due to when plants were constructed. The trended costs I show 13 represent the approximate cost of construction in 2007. As I show in Sheets 1 and 3, the 14 newest steam plant is Iatan, which KCP&L completed in 1980. KCP&L completed its 15 oldest non-steam plant (excluding the Spearville wind farm, the Wolf Creek nuclear 16 station, and the Northeast Station) in 2000. Since 2000, the cost of combustion turbine 17 based generating equipment has increased by about 20 percent (Line 17 of Sheets 1 and 18 3), less than 3 percent per year. The cost of this equipment increased by 300 percent 19 between the mid 1970's to today (Northeast Plant, Sheet 1, Line 17, Column N), more 20 than 15 percent per year. Any meaningful cost comparison between the costs of different 21 technologies should consider and eliminate to the extent practical the implications of 22 inflation on the relative values.

Q. BASED ON EXAMINATION OF SHEETS 3 AND 4 OF SCHEDULE LWL-2, DO YOU REACH ANY CONCLUSIONS?

- A. Yes, I do. In Schedule LWL-2, I demonstrate that based on KCP&L's power supply cost
 and operating characteristics:
- 1) KCP&L's original cost varies dramatically from about \$100 per kW (Northeast)
 to \$2,300 per kW (Wolf Creek). If the implications of inflation are eliminated,
 the construction costs of KCP&L's steam generation amounts to about \$1,750 per
 kW (Sheet 3, Column C, Line 21) which amounts to about 4 times the \$400 per
 kW associated with KCP&L's combustion turbine plants.
- 102)KCP&L's variable cost varies even more dramatically from zero for Spearville, to11\$4.53 per MWH for nuclear generation to over \$300 per MWH for Northeast. For12all of KCP&L's combustion turbine based generation, variable costs amount to13about \$75.00 per MWH or about 6 times the variable costs of KCP&L's steam-14fired generating plants of about \$12.35 per MWH.
- 15 3) Variable costs (\$/kWh) tend to decline as plant costs (\$/kW) increase. Other
 16 generating plant (combustion turbine) variable costs are about 6 times that of
 17 steam plant variable costs whereas steam plant construction (fixed) costs about 4
 18 times that of the combustion turbine based plants.
- 19 4) Capacity factor for the various resources tends to increase as construction (fixed)
 20 costs increase and tends to decrease as variable costs decrease.

The inescapable conclusion based on the information shown in Schedule LWL-1 and confirmed in Schedule LWL-2 is that there is a trade-off between the fixed cost and variable costs. The variable costs associated with high capital cost generating resources are substantially less than from lower capital cost resources. KCP&L incurred high capital costs in order to have resources available to meet capacity requirements <u>as well as</u> to generate energy economically. KCP&L incurs the higher variable costs as a trade off against the lower capital costs associated with resources needed <u>solely</u> to meet peak period requirements.

As I show on Line 13, the capacity factor of KCP&L's steam plants (68.23%) is 16 times that of the combustion turbine based plants (4.24%).

8 In simple terms, KCP&L incurred high capital costs to make energy (MWHs). 9 Conversely, KCP&L did not incur these high capital costs to make MWs (meet peak 10 period requirements) because other lower cost resources are available to use relatively 11 infrequently to meet those needs.

12 Q. CAN YOU FURTHER DEMONSTRATE THIS CONCEPT?

13 A. Yes, I can by reference to Schedule LWL-3. Schedule LWL-3 consists of two sheets. In

14 Sheet 1, I show KCP&L's actual load duration curve. In this graph, I show:

- 15 1) Load associated with Missouri jurisdictional sales (lower curve);
- 16 2) Total native load (center curve); and
- 17 3) Total load including off-system sales (upper curve).

18 Note that as native load decreases the level of off-system sales tend to increase.

Note also that the Missouri load shape is similar to that of the total native load. There
is however, some narrowing of the difference between the Missouri load and total native
load as load levels decline. This is evidence of the somewhat higher load factor for sales
in Missouri relative to other jurisdictions.

Q. DO THE LOAD CURVES YOU SHOW IN SCHEDULE LWL-3 REPRESENT ACTUAL DELIVERIES BY KCP&L DURING 2007?

3 Yes, they do. I did however average hourly loads over certain ranges in order to A. 4 "smooth" the curves. In preparing these curves, I first ranked native load from highest to 5 lowest. For the hour with the highest native load, I plot the Missouri load and total load. For the hour with the second highest native load, I plot the Missouri load and total load. I 6 7 do this for each of the 8,760 hours in 2007, averaging values over various ranges in order 8 to eliminate hourly variations (noise) from the graph. The resulting load curves are an 9 accurate representation of the hourly Missouri and total loads corresponding to the native 10 load.

11

Q. WHAT DO YOU SHOW IN SCHEDULE LWL-3, SHEET 2?

A. In Sheet 2, I start with the total load curve I show in Sheet 1. To that curve, I add generation from KCP&L's various power stations. The order, in which I show the various resources, corresponds to how well hourly generation from that station correlates to the total hourly native load. This "stacking" order generally corresponds from lowest to highest variable cost (highest to lowest fixed and construction cost.)

For example, I show Wolf Creek as the bottom curve. Hourly generation from Wolf Creek has the lowest correlation to KCP&L's hourly native load. In 2007, Wolf Creek generated 8,759⁵ hours. The average load amounted to 556 MW. The maximum load amounted to 566 MW and the minimum load was 436 MW. In 2007, the Wolf Creek

⁵ The hourly load data I relied on included all 8,760 hours. However, hourly generation data for the hour beginning 11:00 PM December 31, 2007 is missing.

plant operated solely as a base load resource, it did not generate in response to changes in native load demands.

1

2

3	Above Wolf Creek, I show Iatan and Spearville. As a wind farm, Spearville does not
4	follow load. I also found that output from Iatan has a very low correlation with native
5	load. Thus, I consider Iatan and Spearville to operate as base load resources. Above
6	Iatan and Spearville, I plot LaCygne and Hawthorn Unit 5. These two plants correlate
7	somewhat with native load, Montrose has a higher correlation, and the other generating
8	resources plus purchases have the highest correlation.
9	Based on the stacking order I show in Sheet 2, I conclude that:
10	• Wolf Creek, Spearville, and Iatan operate as base load resources;
11	• LaCygne and Hawthorn 5 operate as base/intermediate load resources;
12	• Montrose operates somewhere between intermediate and peaking resources; and
13	• Combustion turbine based generation and purchases represent peaking resources
14	that KCP&L relies on to meet peak customer demands in excess of capacity from
15	base and intermediate load units.

OFF-SYSTEM SALES

16 Q. HOW WERE MARGINS ASSOCIATED WITH OFF-SYSTEM SALES 17 ALLOCATED IN THE PRIOR CASE?

18 A. The Company proposed use of "unused sales" as the basis to allocate these margins in
19 Case No. ER-2006-0314, but the Commission rejected this proposal in favor of an

27

allocation based on energy sales. The Kansas Commission accepted the "unused sales"
 method in Docket No. 07-KCPE-905-RTS.

3 Q. DO YOU BELIEVE AN UNUSED SALES ALLOCATION IS REASONABLE?

4 A. No, I do not. However, compared to some other approaches, it produces a more
5 reasonable result than an energy allocation.

6 Q. WHAT FACTOR DETERMINES WHETHER AN ALLOCATION OF THESE 7 SALES MARGINS IS REASONABLE?

8 A. The most critical factor for assessing the reasonableness of the classification and 9 allocation of margin from off-system sales is the extent it is internally consistent with the 10 allocation basis used to allocate fixed costs associated with the Company's generating 11 resources.

12 The credit (revenues) from off-system sales consists of two components. One is the 13 recovery of the out-of-pocket costs associated with generating the energy sold off-system. 14 The second is the revenues in excess of out-of-pocket cost (margin). This margin 15 represents a contribution toward the fixed costs of the Company's generating resources. 16 The allocation of this sales margin must align with the allocation of fixed production 17 costs in order for the allocation to be reasonable. Subsidization results, if this allocation 18 does not align with the allocation of the fixed production costs these margins are intended 19 to offset.

Q. IN YOUR OPINION, DID THE COMMISSION ERR WHEN IT ORDERED USE OF AN ENERGY ALLOCATOR TO ALLOCATE MARGINS ASSOCIATED WITH OFF-SYSTEM SALES?

A. That is a difficult question. I believe the Commission decision is reasonable based on my
understanding of the evidence presented for the Commission's consideration. On the
other hand, the result in both Missouri and Kansas is that the allocation of off-system
sales margins does not align with the responsibility for power supply fixed costs.

8 Q. HAVE YOU EVALUATED THE IMPLICATIONS OF THE ALLOCATION OF 9 THESE SALES MARGINS?

A. Yes, I have. To do so, I developed KCP&L's total revenue requirement based on 2007
operations and a 10.75 percent return on equity. I summarize this development in
Schedule LWL-4. In this schedule, I show that total fixed cost (revenue requirement)
associated with power supply amounts to \$385.7 million and total power supply variable
cost amounts to \$252.2 million. Both of these values represent revenue requirements net
of revenues associated with off-system sales.

In Schedule LWL-5, using the revenue requirement levels I summarize in Schedule LWL-4, I show the impact of the classification and allocation of off-system sales margin to the Missouri jurisdiction. In Lines 1 through 10, I summarize revenue requirements by type of generation, along with the credit for off-system sales⁶. As shown, the total revenue requirement prior to the credit for off-system sales amounts to \$868.0 million. Of this \$868.0 million, \$484.3 million represents fixed costs and \$383.7 million

⁶ In the balance of my testimony, my reference to off-system sales and off-system sales margins, include miscellaneous revenues of \$40,311, see Schedule LWL-4, Lines 22, 23, and 33.

1 represents variable costs. After crediting revenues from off-system sales of \$230.1 2 million net revenue requirements amount to \$638.0 million. Of the \$230.1 million of 3 revenues from off-system sales, \$131.5 million represents the out-of-pocket or variable 4 cost associated with generating the energy sold. The balance (\$98.5 million) represents 5 the margin (revenues in excess of cost) associated with off-system sales. This margin 6 represents a contribution to power supply fixed costs. I therefore credit the variable 7 portion of revenues from off-system sales to variable cost and margin from off-system 8 sales to fixed power supply revenue requirements.

9 On Lines 11 through 19, I show the allocation of power supply costs to the Missouri 10 jurisdiction, if I classify margin associated with off-system sales as energy related and 11 allocate based on annual sales. This is the treatment ordered by the Commission in the 12 prior case. As I show on Line 17, this treatment results in a total credit for off-system 13 sales revenues of \$131.6 million applicable to the Missouri jurisdiction. Following this 14 treatment, I allocate a total of \$349.9 million or 54.85% of total power supply related 15 costs to the Missouri jurisdiction.

On Lines 20 through 28, I show the allocation of power supply costs to the Missouri jurisdiction if I classify margin associated with off-system sales correctly as capacity related and allocate based on coincident peak requirements. As I show in Line 26, this treatment results in a total credit for off-system sales revenues of \$128.5 million applicable to the Missouri jurisdiction. Following this treatment, I allocate a total of \$353.0 million or 55.33% of total power supply related costs to the Missouri jurisdiction. 1 On Lines 29 through 37, I show the development of the capacity and energy 2 allocation factors I use. In this regard, for the purpose of Schedule LWL-5 I use a 4CP 3 allocator to allocate capacity costs.

4 Q. WHAT ARE THE IMPLICATIONS OF CREDITING MARGIN ASSOCIATED 5 WITH OFF-SYSTEM SALES TO ENERGY RELATED COSTS?

6 A. Margins associated with off-system sales represent revenues less out-of-pocket costs. Of 7 the total revenues associated with off-system sales of \$230.0 million, \$131.5 million 8 represents the variable (energy) cost associated with generating the energy sold. As I 9 show in Schedules LWL-4 and LWL-5, I have credited this \$131.5 million to variable 10 cost in order to eliminate the costs associated with making the off-system sales from the 11 costs I allocate among native load customers. Since I recovered the variable costs 12 associated with the sales, the remainder, \$98.5 million represents a contribution to fixed 13 costs. Since there are no fixed costs included in variable or energy related costs, there are 14 no fixed costs for the off-system sales margin to offset. To the extent I reduce variable or 15 energy related cost by off-system sales margin, I would subsidize the sale of energy to 16 native load customers by selling energy below cost.

ENVIRONMENTAL COSTS

17 Q. WHAT ARE ENVIRONMENTAL COSTS?

A. As I use the term in my testimony, environmental costs represent all costs (fixed and
 variable) associated with the capital and operation and maintenance of equipment used in

1		the Company's coal-fired steam generating stations to reduce, control, or monitor plant
2		emissions. These costs include:
3		1) Fixed investment costs (depreciation, return, and taxes) associated with:
4		• Flue gas desulphurization (FGD or scrubbers) equipment;
5		• Selective catalytic reduction (SCR) equipment;
6		• Other NO_x control equipment;
7		• Particulate control equipment; and
8		• Facilities, equipment, land, and improvements associated with the disposal of
9		products produced by the equipment identified above;
10		2) Variable costs associated with consumables used by the facilities and equipment
11		listed in 1) above;
12		3) Fixed operation and maintenance expenses associated with the operation and
13		maintenance of the facilities and equipment listed in 1) above;
14		4) Allowances purchased; and
15		5) Allowances sold (credit).
16	Q.	WHAT DO YOU RECOMMEND AS THE BASIS TO CLASSIFY AND
17		ALLOCATE THESE ENVIRONMENTAL COSTS?
18	A.	Environmental costs, both fixed and variable, should be allocated on a basis that
19		recognizes the nature of these costs.
20	Q.	WHAT IS THE NATURE OF THESE COSTS?
21	٨	KCD&L incurs these environmental control cost in connection with the concretion of

A. KCP&L incurs these environmental control cost in connection with the generation of
electricity from its coal-fired steam generating stations. KCP&L does not incur these

costs in order to supply power to customers for 4 hours or even 12 hours a year. The
 need for this equipment relates to the total energy generated at each of the stations. As a
 result, these costs are energy related and should be allocated accordingly.

4 Q. ARE THERE ANY FACTORS THAT DEMONSTRATE THE ENERGY 5 RELATED NATURE OF THESE COSTS?

A. Yes, there are. In lieu of incurring capital costs to control emissions, KCP&L could
purchase allowances. The cost of purchasing allowances is directly related to the kWh
generated because for each additional kWh generated, KCP&L would need to purchase
an additional fraction of an allowance.

10 Q. HAVE YOU EVALUATED THE IMPLICATIONS OF CLASSIFYING 11 ENVIRONMENTAL COSTS AS ENERGY?

A. Yes, I have. In Schedule LWL-6, I show the impact of the classification and allocation of environmental costs based on energy sales to the Missouri jurisdiction. Lines 1 through 24 of Schedule LWL-6 are identical to Lines 1 through 19 of Schedule LWL-5 with the exception that I have split the revenue requirement associated with steam generation into fixed environmental costs and other steam generation costs. In this regard, I estimate that fixed environmental costs amount to 32 percent of total steam fixed costs.

I show in Lines 25 through 37, of Schedule LWL-6 the classification and allocation of fixed environmental costs based on annual energy sales. In this allocation, I have also classified the margin on off-system sales as capacity, and allocated accordingly.

Q. LINES 9 AND 22 OF SCHEDULE LWL-5 SHOWS CAPACITY RELATED OFFSYSTEM SALES OF \$98.5 MILLION WHEREAS, LINE 29 OF SCHEDULE

33

LWL-6 SHOWS CAPACITY RELATED OFF-SYSTEM SALES OF \$79.8 MILLION. WHY ARE THESE CREDITS DIFFERENT?

3 A. Recall that I recommend allocating the margin associated with off-system sales on the 4 same basis as the fixed costs associated with the resource(s) supplying the power and 5 energy sold. In Schedule LWL-5, I classify all power supply fixed costs as capacity 6 related and allocate these capacity costs based on coincidental peak demand (4CP). In 7 Schedule LWL-6 however, I do not classify all power supply fixed costs as demand 8 related. In Schedule LWL-6 (Line 28), I classify \$75.0 million of fixed power supply 9 costs (environmental) as energy related. During 2007, about 25 percent of power 10 generated by KCP&L went to support off-system sales. I have therefore classified off-11 system sales margin equal to 25 percent of the fixed environmental costs as energy 12 related. This treatment recognizes that I have now classified certain fixed costs as energy 13 related, and that associated off-system sales margin should follow. The remaining 14 margin associated with off-system sales (\$79.8 million) I classify as capacity related.

On Lines 25 through 37, I show the allocation of power supply costs to the Missouri jurisdiction, if I classify fixed environmental cost as energy and classify margin associated with off-system sales on the same basis as fixed power supply costs. As I show in Line 37, this results in allocating 55.60 percent (\$354.7 million) of power supply costs to the Missouri jurisdiction.

BOILER MAINTENANCE

1	Q.	HOW ARE EXPENSES ASSOCIATED WITH BOILER MAINTENANCE
2		USUALLY ALLOCATED?
3	A.	These maintenance expenses are usually considered fixed, classified as demand related,
4		and allocated based on peak demands.
5	Q.	DO YOU AGREE WITH THIS TREATMENT?
6	A.	No. I believe that for the most part, boiler maintenance activities represent a variable
7		cost. By variable cost, I mean costs that tend to change in response to the energy
8		generated by steam produced by the boiler.
9	Q.	PLEASE EXPLAIN.
10	A.	Boiler maintenance requirements (and to some degree boiler life) tend to vary depending
11		on the total steam produced. This is because, one of the biggest factors that affect the
12		need for maintenance relates to erosion of boiler tubes from the inside by the water and
13		steam flowing through them and from the outside by the particles of combustion and flue
14		gas. As a result, in large part, maintenance requirements depend on the total energy
15		generated.
16	Q.	DO YOU CONSIDER ALL BOILER MAINTENANCE EXPENSES VARIABLE
17		IN NATURE?
18	A.	No, I do not. Boiler maintenance consists of KCP&L labor and non-labor components
19		(materials and non-KCP&L labor). The KCP&L labor component represents the cost of
20		KCP&L employees performing maintenance activities. This labor cost is relatively fixed

35

since the employees used to perform boiler maintenance activities are involved in other activities during periods when the boiler is not undergoing maintenance.

The other component relates to maintenance contracts and materials used in maintenance activities. These costs relate directly to the need for maintenance and if maintenance were not required, these costs would not be incurred.

6

Q.

1

2

WHY DO YOU CONSIDER THIS MAINTENANCE COST VARIABLE?

7 A. With regard to both the boiler and turbine, one of the principal needs for maintenance 8 relates to erosion. Erosion is the process of weakening a material (in this case steel) 9 because of material, water, and products of combustion wearing it away. In order to keep 10 this equipment running, maintenance is required to replace eroded boiler tubes and 11 turbine vanes. Much like the automobile manufacturers' requirement to change oil in 12 cars based on mileage, boiler and turbine manufacturers typically base maintenance 13 schedules and maintenance contracts on the number of hours connected to load and/or 14 number of starts.

Manufacturers also base maintenance schedules and contracts on the number of starts a plant undergoes. Starting and stopping plants introduces thermal stresses due to the heating and cooling of parts. These thermal stresses also increase maintenance requirements. Because of the frequent starts and stops experienced by peaking facilities, the number of starts tends to govern maintenance requirements of peaking equipment.

For large steam plants operated as base load resources, it is the number of hours loaded that controls the need for maintenance. Base load units are not subject to frequent starts. Thus, these activities (boiler maintenance) are properly related to the energy produced by steam generating units and should be allocated accordingly.

36

1Q.ARE THERE ENERGY RELATED MAINTENANCE REQUIREMENTS2ASSOCIATED WITH POWER SUPPLY EQUIPMENT OTHER THAN3BOILERS?

A. Yes, to some degree. Manufacturers typically base maintenance schedules associated
with turbine generators and combustion turbines on the number of starts and/or number
of hours connected to load. Since KCP&L uses its CT based equipment to meet peaking
requirements, maintenance of these peaking units is based on the number of starts, hence
appropriately allocated based on peak period demands. With regard to steam plants,
maintenance associated with equipment other than boilers is relatively minor.

10 I therefore recommend that non-labor boiler maintenance costs be classified as energy
11 and allocated based on energy sales.

12 Q. HAVE YOU EVALUATED THE IMPLICATIONS OF CLASSIFYING THE NON 13 LABOR COMPONENT OF BOILER MAINTENANCE EXPENSES ON 14 ENERGY?

A. Yes, I have. In Schedule LWL-7, I show the impact of the classification and allocation of
the non-labor portion of boiler maintenance expenses as energy related and allocate such
expenses based on energy deliveries. The schedule also reflects recognition of the nature
of the margin on off-system sales and environmental costs.

Lines 1 through 27 of Schedule LWL-7 are identical to Lines 1 through 19 of Schedule LWL-5 (Lines 1 through 24 of Schedule LWL-6) with the exception that I have split the gross revenue requirement associated with steam generation into boiler maintenance, environmental cost, and other.

1	I show on Lines 28 through 34, of Schedule LWL-7 the classification of the non-labor
2	portion of boiler maintenance expenses based on energy. In this regard, for the purpose
3	of this schedule, I estimate that 50 percent of boiler maintenance expenses relate to
4	KCP&L labor and 50 percent to non-labor expenses. I also recognize that a portion of
5	boiler maintenance expense relates to environmental equipment. In this allocation, I have
6	also classified the margin on off-system sales as capacity related and environmental costs
7	as energy related and allocated accordingly.
8	As with Schedule LWL-6, because of changing the classification of fixed power
9	supply costs, the classification of margin on off-system sales changes accordingly.
10	On Lines 35 through 42, I show the allocation of power supply costs to the Missouri
11	jurisdiction, if I classify the non-labor portion of boiler maintenance and fixed
12	environmental cost as energy and classify margin associated with off-system sales on the
13	same basis as fixed power supply costs. As I show on Line 42, this treatment results in
14	allocating 55.64 percent of power supply costs to the Missouri jurisdiction.

CAPACITY RELATED POWER SUPPLY COSTS

15 Q. WHAT ARE CAPACITY RELATED POWER SUPPLY COSTS?

A. When I refer to capacity related power supply costs, I am referring to fixed costs that are
allocated on some basis that recognizes maximum demands placed on the system. Peak
demands, whether 1CP, 4CP, 12CP, or NCP (non-coincident peak demands), are
measures of maximum system demand usually used to allocate capacity related costs.

1

2

The Commission adopted the 4CP method in KCP&L's 2006 rate case case (ER-2006-0314), whereas the Kansas Commission has adopted the 12CP method.

3 Q. HAVE YOU EVALUATED THE IMPLICATIONS OF USING THESE VARIOUS 4 COINCIDENTAL PEAK ALLOCATION BASES?

A. Yes, I have. In Schedules LWL-5, 6, and 7, I show the impact of using the coincident
peak demand for the 4 summer months to allocate capacity related costs. In Schedule 8, I
show the impact of using the contribution to the maximum annual peak demand (1CP,
Sheet 1) and the contribution to each month's maximum demand (12CP, Sheet 2).

9

Q. WHAT ARE THE IMPLICATIONS OF USING THE 1CP METHOD?

A. As I show in Schedule 8, Sheet 1, Line 14, using a single CP allocator and assuming an
 energy allocation of off-system sales and a capacity allocation of environmental and
 boiler maintenance cost, the cost responsibility allocated to the Missouri jurisdiction
 amounts to \$349.4 million, or 54.77 percent of the total power supply net revenue
 requirement.

Assuming the allocation recognizes the nature of off-system sales, environmental cost, and boiler maintenance, the cost responsibility allocated to the Missouri jurisdiction amounts to \$354.6 million (Line 29), or 55.58 percent of the total power supply net revenue requirement.

19

Q. WHAT ARE THE IMPLICATIONS OF USING THE 12CP METHOD?

A. As I show in Schedule 8, Sheet 2, Line 14, assuming an energy allocation of off-system
sales and a capacity allocation of environmental and boiler maintenance costs, the cost

responsibility allocated to the Missouri jurisdiction amounts to \$351.6 million, or 55.11
 percent of the total power supply net revenue requirement.

Assuming the allocation recognizes the nature of 1) off-system sales, 2) environmental cost, and 3) boiler maintenance, the cost responsibility allocated to the Missouri jurisdiction amounts to \$356.1 million (Line 29), or 55.81 percent of the total power supply net revenue requirement.

7 Q. WHICH OF THESE APPROACHES DO YOU CONSIDER MOST 8 APPLICABLE?

9 A. For predominately summer peaking utilities, I prefer the single or four coincident peak
10 method to the 12CP method. For the purpose of this case, I recommend use of the 4CP
11 allocation basis. The Missouri Commission relied on the 4CP method in KCP&L's prior
12 two rate cases (ER-2006-0314 and ER-2007-0291). Further, to the extent coincidental
13 peak demands are relied on to allocate demand related cost, I believe that the 4CP is more
14 stable than a single CP allocation basis.

15 Q. DID YOU EVALUATE ANY OTHER POWER SUPPLY CLASSIFICATION AND 16 ALLOCATION APPROACHES?

17 A. Yes, I did. I evaluated four other approaches. I refer to these four approaches as the:

- 18 1) Capital substitution method;
- 19 2) Base, intermediate, peaking method;
- 20 3) Economic rents method; and
- 21 4) Hour-by-hour method.

1Q.PLEASE DESCRIBE WHAT YOU REFER TO AS THE CAPITAL2SUBSTITUTION METHOD.

3 A. As I previously discussed, a utility's fixed power supply cost is determined by two 4 factors. One factor is the maximum system demand. The second factor is the mix of 5 generating resources required to meet its energy requirements economically. The capital 6 substitution method explicitly recognizes both of these factors. It is based on the premise 7 that utilities do not construct expensive base load generating resources to meet system 8 In order to meet peak demands, utilities construct less expensive peak demands. 9 resources. The capital substitution method is based on the straightforward concept that 10 the cost responsibility associated with peak requirements should recognize the cost 11 associated with the facilities the utility actually constructs and uses to meet those 12 demands. Costs in excess of the cost of peaking are then classified as energy and 13 allocated based on annual energy sales.

14 Q. WHAT ARE THE IMPLICATIONS OF CLASSIFYING COSTS BASED ON USE 15 OF THE CAPITAL SUBSTITUTION METHOD?

A. In Schedule LWL-9, I show the classification of power supply costs into capacity and
 energy related and the subsequent allocation of costs to the Missouri jurisdiction using
 the capital substitution method. I allocate costs classified as capacity related based on the
 Missouri's contribution to the 4CP demand.

In Schedule LWL-9, I first show power supply cost by generating type (Lines 1 through 10). On lines 1 through 8, I show gross revenue requirements before the credit for off-system sales. I next show, on Lines 11 through 18, units of service corresponding to the gross revenue requirements I show in Lines 1 through 8. In this regard, I show in

41

Column D, KCP&L's accredited summer capacity for each type of generating resource.
 In Column E, I show annual generation from each type of resource. In Column C, I show
 "capacity factor" based on annual generation and accredited capacity.

4

Q. IS ACCREDITED CAPACITY AND CAPACITY FACTOR CRITICAL?

A. Accredited capacity is the measure of the amount of generating resources KCP&L has to
meet customers' peak requirements. If accredited capacity is not sufficient to cover
customers' peak demands and provide an adequate reserve margin, KCP&L must acquire
additional resources. Therefore accredited capacity represents the measure of the total
capacity required to meet customers' requirements.

10 Capacity factor on the other hand provides information regarding which resources are 11 peaking in nature. As I show, the capacity factor (based on accredited capacity) for other 12 generation (peaking) amounts to less than 5 percent, whereas other types of generating 13 resources all exceed 70 percent. A five percent capacity factor clearly relates to 14 resources operated as peaking.

15 Q. WHAT DO YOU SHOW IN LINES 19 THROUGH 26?

A. In Lines 19 through 26, I show the unit costs for each of the various types of resources.
Unit total costs, Column C represents the total costs (fixed and variable) for the resource
divided by annual generation. As I show, the unit cost of the peaking resources amounts
to nearly 20 cents per kWh, whereas the average for the other resources amounts to about
3.5 cents per kWh.

In Column D, I show unit fixed costs based on accredited capacity. Of particular note
is the \$53.95 per kW fixed cost of peaking resources. This unit cost represents the unit

1		capacity cost of KCP&L's facilities installed to meet customer's peak period
2		requirements. This \$53.95 per kW peaking cost compares to a \$136.31 per kW average
3		for KCP&L's other resources.
4		In Column E, I show unit variable costs for each of the various types of generating
5		resources.
6	Q.	DO YOU USE THESE UNIT COSTS?
7	A.	Yes, I use the unit cost of peaking (\$53.95 per kW) to develop capacity related cost. I
8		calculate capacity related cost (\$232.4 million, Line 29) as the product of the unit cost of
9		capacity (\$53.95 per kW) and KCP&L's total accredited capacity (4,308 MW). I then
10		determine energy related cost as the balance of fixed cost plus variable cost. I reach the
11		same result by reducing the total revenue requirement of \$638.0 million by the capacity
12		related cost of \$232.4 million.
13		I show on Line 33, that following the capital substitution method, capacity related
14		costs amounts to \$232.4 million and energy related costs amount to \$405.5 million. I
15		complete Schedule LWL-9 by allocating capacity related and energy related costs to the
16		Missouri jurisdiction.
17		I show on Line 39, total cost allocated to the Missouri jurisdiction amounts to \$357.7
18		million or 56.07 percent (Line 35) of total power supply revenue requirements.

Q. IN SCHEDULE LWL-9, YOU SHOW MARGIN ASSOCIATED WITH OFF SYSTEM SALES AS A FIXED COST. HOW HAVE YOU TREATED ENVIRONMENTAL CONTROL AND BOILER MAINTENANCE COSTS?

4 A. Following my capital substitution method, the treatment of off-system sales, 5 environmental cost, and boiler maintenance is of no consequence. As I suggested 6 previously, the capital substitution method is in fact a method to classify cost. This 7 method recognizes the fact that fixed costs of power supply are affected not only by the 8 maximum demand placed on the system by customers, but also on the energy 9 requirements of such customers. Using the capital substitution method, there is no issue 10 regarding the classification of margin on off-system sales, environmental cost, and boiler 11 maintenance. In the classification and allocation I show in Schedule 9, I have allocated 12 capacity costs as determined by the unit cost of peaking capacity and KCP&L's 13 accredited capacity based on the maximum demands during the summer months (4CP). I then allocate the balance of power supply costs based on energy sales. To the extent that 14 15 costs are included in the cost of peaking resources, they are classified as demand related 16 and allocated accordingly. For all other costs, fixed and variable, I consider these to be 17 energy related. Thus following the capital substitution method, the manner in which I 18 classify costs (except for fixed costs associated with peaking resources) has no bearing.

19

Q. PLEASE DESCRIBE THE BASE, INTERMEDIATE, PEAKING METHOD.

A. The premise underlying the base, intermediate, peaking ("BIP") method is that there are
 three basic types of generating resources. These resources are operated differently and
 have differing cost characteristics. The BIP method recognizes these different costs and

1

2

operating characteristics by allocating costs associated with each type of generation separately according to each jurisdiction's use of that type of generation.

3 As I previously discussed, base load resources are operated throughout the year. Base 4 load resources are seldom shut down except as a result of forced outage or maintenance. 5 Output from base load resources does not vary materially in response to changes in 6 customers' load. Base load resources are characterized by high capital cost and low 7 operating costs. The benefit of base load resources is the energy produced. Therefore 8 following the BIP method, the costs of base load resources are allocated primarily based 9 on energy requirements. These energy requirements are at the bottom of the load curve. 10 As I show in Schedule LWL-3, Sheet 2, the Wolf Creek nuclear unit, the Spearville wind 11 farm, and the Iatan Unit 1 operate as base load resources.

12 Peaking resources on the other hand are designed and operated to meet the high 13 demands placed on the system a relatively few hours a year. Peaking resources often will 14 be started and stopped daily or weekly in response to customer loads. As I previously 15 described, peaking generation is characterized by low capital cost but high operating 16 costs. Peaking resources are called upon to meet customers' requirements in excess of 17 requirements met by base load and intermediate resources. Following the BIP approach, 18 I allocate the cost of peaking resources based on customers' requirements in excess of 19 what base and intermediate load resources provide.

Between base load and peaking load resources are what I refer to as intermediate load resources. This generating equipment tends to follow load by increasing or decreasing output throughout the day. Utilities seldom add generating equipment to meet intermediate load service. More often than not, intermediate load service requirements are met by older less efficient generating units which were originally installed to provide
 base load service. The costs of intermediate load resources tend to fall between the costs
 of base load and peaking resources.

4 Q. HAVE YOU EVALUATED THE IMPLICATIONS OF THE BIP METHOD ON 5 THE MISSOURI JURISDICTION?

6 A. Yes, I have. I show the results of my BIP allocation in Schedule LWL-10.

In reviewing the operation of KCP&L's generating resources, I found that as
expected, the Wolf Creek nuclear plant, the Spearville wind farm, and Iatan I all operate
as base load resources. None of these resources are used to follow load to any significant
extent.

During 2007, the combined output from these three resources at no time exceeded native load. The capacity factor for Wolf Creek exceeded 95 percent whereas the capacity factor for Iatan amounted to about 65 percent. However, Iatan's capacity factor during the hours it was connected to load exceeded 85 percent.

KCP&L uses its LaCygne and Hawthorn 5 units to meet the remainder of customers' base load requirements as well as provide intermediate load service. To some limited degree, these two units follow load and are connected to load nearly continuously (LaCygne – 8,284 hours and Hawthorn 5 – 7,590). When connected to load, the capacity factor for the LaCygne station amounted to about 75 percent where as the capacity factor for the Hawthorn 5 unit amounted to over 80 percent.

KCP&L uses its Montrose plant to meet the remainder of its intermediate load
 requirements. The plant was connected to load for over 8,000 hours during 2007.
 However, the capacity factor (based on connected hours) amounted to 67 percent.

46

Examination of the hourly load curves shows that to some degree KCP&L operates the
 plant to follow load.

KCP&L operates the remainder of its generating resources to meet customer's
peaking requirements. Of these CT and internal engine based resources, no unit was
connected to load for over 2,500 hours, and only one (Hawthorn 6 & 9 – 2,471 hours),
was connected to load for over 500 hours.

7 Q. IN DEVELOPING THE BIP ALLOCATION, WHAT WAS YOUR FIRST STEP?

8 I first developed revenue requirements by the four classes of generation I identified (base, A. 9 base/intermediate, intermediate/peaking, and peaking.) I summarize those revenue 10 requirements on Lines 7 through 12 of Schedule LWL-10. To these revenue 11 requirements, I apply allocation factors which recognize the Missouri jurisdiction's use of 12 each of these resources. As I show on Lines 13 through 17, the Missouri jurisdiction's 13 responsibility ranges from a little over 40 percent for peaking demand related cost to 14 about 61 percent for the cost associated with base load resources.

I show on Line 23 that the Missouri jurisdiction's responsibility amounts to \$353.8
million or 55.46 percent.

17 Q. HOW DO YOU DEVELOP THE ALLOCATION FACTORS YOU SHOW ON 18 LINES 13 THROUGH 17?

A. I develop the allocation factors based on the use of capacity and energy of each type of
generation by the Missouri jurisdiction. To do so, I start with the load duration curve I
show in Schedule LWL-3, Sheets 1 and 2. Based on that curve, I find that the load on the
base load resources at the time of the minimum native load amounts to 904 MW, whereas

1

2

at the time of the native load's maximum demand the base load resources generated 1,065 MW or 17 percent more than the minimum.

I also find that the minimum native load amounts to 1,114 MW, whereas the Missouri 3 4 contribution to that native load amounts to 679 MW, or 61.0 percent of minimum native 5 load. The output from the base load resources at the time of the native load's maximum demand is 17 percent higher than the load at the time of the native load's minimum 6 7 demand. As a result, at the time of the native load peak demand I set the Missouri jurisdiction's load at 17 percent more than the level I determined as the minimum 8 9 associated with base load resource. Based on the minimum and maximum loads for the 10 Missouri jurisdiction and native load, and the shape of the load curve for the base load 11 resources, I develop load curves for use of base load resources by Missouri and total 12 native load. From these load curves, I determine the energy from base load resources 13 attributable to Missouri as well as the maximum loads.

I repeat this process to determine the Missouri jurisdiction's responsibility for each of the other resources' load at the time of native load maximum demand, as well as the use of energy.

17

7 Q. PLEASE DESCRIBE THE ECONOMIC RENTS METHOD.

A. The economic rents method is much like a unit capacity sale. A unit capacity sale is a contractual arrangement where the purchaser, in return for paying X percent of the fixed and variable costs of a generating station, gets X percent of the plant's output. The economic rents approach is based on the same concept. Based on the demand responsibility, each jurisdiction is credited with all of the energy produced.

1	Q.	IF THE	MISSOUR	I JURISDI	CTION	N IS C	REDITED	WITH	ENERGY
2		PRODUC	ED IN PRO	OPORTION	TO I	TS DEN	IAND RE	SPONSIB	ILITY, IS
3		THERE	ENOUGH	ENERGY	ТО	MEET	MISSOU	RI CUS	TOMERS'
4		REQUIR	EMENTS?						

A. No, there is not. That is why a "transfer pricing mechanism" is required. In this regard, I
use the equivalent cost at 100 percent load factor operation. This results in a contribution
to the fixed costs charged to the other jurisdictions and the cost of the energy needed by
the Missouri jurisdiction as if generation were operated at the 100 percent load factor.

9 Q. HAVE YOU PREPARED A SCHEDULE SHOWING THE RESULTS OF THIS 10 APPROACH?

11 A. Yes, I have.

In Schedule LWL-11, I show the application of this method. I begin with the revenue
requirements and the total units of service (Lines 1 through 9). On Lines 11 and 12, I
show the unit cost per kW and per kWh.

As I indicated above, in order to satisfy Missouri's energy requirements, a transfer pricing is required. In Schedule LWL-11, I used the 100 percent load factor equivalent cost as the transfer price. I calculate this 100 percent load factor equivalent cost by dividing fixed costs per kW by 8,760 hours, and adding the per-unit variable cost. In this regard, based on the 4CP average demands of 3,450 MW, the 100 percent load factor equivalent cost amounts to 3 cents per kWh.

On Line 19, I show the cost responsibility to the Missouri jurisdiction based on the
4CP allocation factor. On Line 20, I show the associated energy.

49

1 As I show on Line 20, the energy associated with the 54.10 percent of fixed costs that 2 are allocated to Missouri amounts to 8.8 million MWH. This 8.8 million is deficient in meeting the Missouri jurisdiction's requirements by 504,402 MWH (Line 21). The value 3 4 (cost) of this 504,402 MWH amounts to \$15.2 million dollars based on the 100 percent 5 load-factor equivalent cost of 3.01 cents per kWh. Adding the \$15.2 to the \$345.1 6 million responsibility based on the 4CP allocation of all costs results in a cost 7 responsibility to the Missouri jurisdiction of \$360.3 million or 56.48 percent.

8

PLEASE DESCRIBE THE HOUR-BY-HOUR METHOD. **Q**.

9 A. The hour-by-hour method is based on the contribution of each generating source to each 10 hour's load. I first allocate the cost of each generating resource to each hour of the year. 11 I do this by dividing the revenue requirements for each resource by the total annual 12 generation from that resource. I then multiply this unit cost by the resource's hourly 13 output to determine the cost in that hour for that generating resource. By adding the costs 14 for all generation in an hour, I develop the total cost for the hour. I allocate this hourly 15 cost to each jurisdiction based on the load of that jurisdiction in that hour.

16 In Schedule LWL-12, I show the results of this method. As I show on Lines 45 and 17 46, the annual cost applicable to the Missouri jurisdiction amounts the \$362.0 million, or 18 56.74 percent of the total.

HAVE YOU SUMMARIZED THE RESULTS OF THE VARIOUS ALLOCATION

19 **Q**.

20

APPROACHES YOU DISCUSSED?

21 Yes, I have. In Schedule LWL-13, I show this summary. A.

As I show in Schedule LWL-13, the Missouri jurisdictional responsibility based on
 the 12 approaches I discuss range from 54.77 percent to 56.74 percent.

Of the methods I show in this Schedule, with the exception of the single CP allocation, the lowest responsibility is using the method approved by the Commission in the Company's 2006 case (ER-2006-0314). Giving no consideration to the 1CP and 12CP approaches, the lowest cost responsibility is from use of the 4CP approach. If the 4CP approach is used and the nature of the off-system sales margin, environmental costs and boiler maintenance is recognized the Missouri cost responsibility amounts to 55.64 percent.

10 Q. DO YOU BELIEVE THAT THE 4CP METHOD PRODUCES REASONABLE 11 RESULTS?

A. The 4CP method, reflecting the proper treatment of off-system sales, environmental and
 boiler maintenance costs, results in a Missouri jurisdictional responsibility of 55.64
 percent. This represents total costs allocated to the Missouri jurisdiction of \$354.9
 million, an increase of \$5.0 million or 1.4 percent above the level reflected in the method
 underlying the existing rates.

Of the other methods I present, the capital substitution method I believe the most reliable and fair, because of its straight forward simplicity and its explicit recognition of the cost implications associated with the various types of generating resources. Using the capital substitution method would result in an additional increase of \$2.8 million (0.8 percent). In order to avoid undue disruption, I recommend that the Commission for the purpose of this case rely on the 4CP method, giving recognition to the nature of offsystem sales margins, environmental costs, and non-labor boiler maintenance as I
 discussed.

ALLOCATION OF TRANSMISSION SYSTEM COSTS

3 Q. HOW ARE TRANSMISSION SYSTEM COSTS USUALLY ALLOCATED?

- A. Transmission costs are typically allocated based on capacity requirements. Most often,
 the basis used to allocate transmission system costs is the same as the allocator used for
 production fixed costs.
- 7

Q. DO YOU BELIEVE THIS TREATMENT REASONABLE?

A. Yes, allocating transmission system cost based on the allocation of power supply fixed
costs has merit. The transmission system serves to link power supply to the load centers.
To the extent that power supply costs are considered energy related, transmission costs
should be treated similarly.

12 The benefit of transmission is two-fold. First, the transmission system tends to 13 reinforce the distribution system. Second, the transmission system serves to link 14 remotely located large central station generating plants to load centers. These large 15 stations are often remotely located due to the difficulty in siting them near major load 16 centers. The primary benefit of these large stations is the relatively low cost of energy 17 produced. To the degree the transmission system serves to connect the large generating 18 stations to load centers, the allocation of transmission system costs should recognize the 19 benefits of those stations. Therefore, I recommend that transmission system costs be 20 allocated on the basis of the allocation of fixed power supply costs.

52

RECOMMENDED ALLOCATION BASES

1Q.BASED ON YOUR INVESTIGATION IN THIS CASE, WHAT2JURISDICTIONAL ALLOCATION BASES DO YOU RECOMMEND THE3COMMISSION ADOPT?

4 A. I recommend the following:

- 5 1) Allocate capacity related power supply costs on the basis of the Missouri 6 jurisdiction's contribution to the four summer month coincident peak demands.
- 7 2) To avoid the subsidization of Missouri customers by KCP&L or other 8 jurisdictions, classify the margin associated with off-system sales in the same 9 manner as the fixed costs associated with KCP&L's generating resources used to 10 generate the energy sold off-system. Since most fixed costs associated with 11 generation are classified as capacity and allocated based on peak period demands, 12 most of the margins associated with off-system sales should be classified as 13 capacity.
- 14 3) Classify steam plant production costs related to environmental protection and15 control as energy related and allocate accordingly.
- 16 4) Classify steam plant boiler maintenance expense excluding KCP&L labor as
 17 energy related and allocate accordingly.
- 18 5) Classify and allocate transmission system costs on the same basis as the
 19 classification and allocation of fixed production related costs.

1	6)	In future rate cases, the Commission should consider allocation approaches that
2		provide explicit consideration to the fact that an electric utility pays a premium
3		for power generating facilities that can produce energy economically.

4 Q. DOES THIS CONCLUDE YOUR PREPARED DIRECT TESTIMONY?

5 A. Yes, it does.

BEFORE THE PUBLIC SERVICE COMMISSION OF THE STATE OF MISSOURI
