4.1 INTRODUCTION

4.1.1 Objectives

Resource integration of demand-side and supply-side resource options was performed by Aquila Networks - Missouri (ANM) as part of the 2007 Integrated Resource Plan. This volume is filed in compliance with the rules for Electric Utility Resource Planning (4 CSR 240-22.060) of the Missouri Public Service Commission. These rules require electric utilities to design resource plans to meet the planning objectives identified in 4 CSR 240-22.010(2), and set minimum standards for the scope and level of detail required in resource plan analysis, and for the logically consistent and economically equivalent analysis of resource plans. Appendix 4-A contains responses to each reporting requirement, referring to appropriate documentation within this report. Appendices 4-B through 4-F provide detailed results for the resource integration analysis.

ANM's 2007 Integrated Resource Plan is based on alternative energy resource plans that are designed to satisfy the objectives and priorities identified in 4 CSR 240-22.010(2), as follows:

- (2) The fundamental objective of the resource planning process at electric utilities shall be to provide the public with energy services that are safe, reliable and efficient, at just and reasonable rates, in a manner that serves the public interest. This objective requires that the utility shall --
- (A) Consider and analyze demand-side efficiency and energy management measures on an equivalent basis with supply-side alternatives in the resource planning process;
- (B) Use minimization of the present worth of long-run utility costs as the primary selection criterion in choosing the preferred resource plan; and
- (C) Explicitly identify and, where possible, quantitatively analyze any other considerations which are critical to meeting the fundamental objective of the resource planning process, but which may constrain or limit the minimization of the present worth of expected utility costs . . .

As required by the Commission's rules, the primary objective utilized by ANM in developing the optimal energy plan was minimization of the present value of revenue requirements over the 2007-2026 planning period. In addition to this

objective, alternative resource plans (ARPs) were also developed for other important planning objectives, as follows:

- Minimize CO₂ production The "No New Coal Generation" ARP prohibits the addition of new coal-fired resources and thus lowers the systemwide production of CO₂. The "Green" ARP examines the cost impact of ANM unilaterally setting its own CO₂ emission rate limit at 6.5 million tons per year beginning in 2015, equivalent to the ANM level of CO₂ emissions in the year 2000.
- Minimize dependence on natural gas The "No New Gas Generation"
 ARP provides an alternative plan for ANM to not increase its exposure to
 the volatile natural gas market in the generation of electricity.

4.1.2 Performance Measures

The alternative resource plans contained in Part 4, Resource Integration, were evaluated based on several performance measures. These performance measures were developed over the 2007-2026 planning period in accordance with 4 CSR 240-22.060(2), and other sections of the Commission's rules, as follows:

<u>Customer Value Measures (Rate Impacts)</u>

- Present value of Utility Revenue Requirements
- Present value of Probable Environmental Costs
- Present value of DSM Program Participant Costs
- Average Rates (annual, levelized and maximum increase)

Environmental Impacts (Annual emissions: Tons, \$Cost)

- Sulfur dioxide (SO₂)
- Nitrogen oxide (NOx)
- Mercury (Hg)
- Carbon dioxide (CO₂)

The above performance measures were calculated over the 2007-2026 planning period for each alternative resource plan using Global Energy Decisions' MIDAS Gold™ software package. Probable environmental costs were included in the resource integration process to determine the selection of demand-side and supply-side resources in the Alternative Resource Plans.

4.1.3 Resource Integration Process

The resource integration process is automated in the MIDAS Gold™ software to comply with the requirement in 4 CSR 240-22.010(2)(A) of the rules. This section of the rules states that the utility shall consider and analyze demand-side efficiency and energy management measures on an equivalent basis with supply-side alternatives in the resource planning process. In addition, section 4 CSR 240-22.060(4)(D) requires that:

The modeling procedure shall treat supply-side and demand-side resources on a logically consistent and economically equivalent basis. This means than the same types or categories of costs, benefits and risks shall be considered, and that these factors shall be quantified in a similar level of detail and precision for all resource types.

The energy planning process for electric utilities includes the following basic steps:

- (1) Prepare a baseline load forecast without demand-side programs.
- (2) Develop an optimal supply-side plan, as a reference plan, without demand-side programs, based on a desired planning objective. (Part 2 of the IRP)
- (3) Develop avoided cost estimates using the system planning method for use in evaluating demand-side measures.
- (4) Evaluate the cost-effectiveness of demand-side resources and develop an initial demand-side plan, based on the avoided costs from the optimal supply-side plan developed in step #2.
- (5) Subtract the effects of cost-effective demand-side resources, identified in step #4, from the baseline load forecast to arrive at a net load forecast.
- (6) Re-optimize the supply-side resources to meet the net load forecast from step #5, considering the load impacts of cost-effective demandside programs
- (7) Conduct a risk analysis to determine the optimal energy plan with the greatest flexibility in coping with uncertainties. (Part 5 of the IRP)

This section of the IRP details the results of steps 5, 6, and 7 from above.

4.2 RESOURCE INTEGRATION

4.2.1 Demand-Side Management Programs

The Demand-Side Management Programs identified in Part 2 were evaluated against the supply-side resources using the MIDAS Gold production cost model. The programs were modeled individually to determine the impact of each program on the net present value of revenue requirements. The model allowed for the delay or elimination of supply-side resource additions as a result of the DSM impact. The only DSM program that was not determined to be cost effective was the direct load control (DLC) program. Table 4-2 provides an overview of the DSM program impacts on ANM-system demand and energy along with the total costs of the cost-effective programs.

Table 4-1
Impact of Demand-Side Management Programs

^[1] The sum of Energy Efficiency and Demand Response Demand Impact do not equal the total peak reduction due to non-coincidence of the program impacts.

The costs and benefits that would be realized by the program participants are shown in Table 4-2. It should be noted that this table does not include the benefit of incentives paid to participants by ANM in the curtailable rates programs.

The summer and winter peak demand impacts of the cost-effective demand-side management programs are shown in Figures 4-1 and 4-2. The impact represents an average annual peak demand growth reduction from 2.0% to 1.6% over the study period. Figure 4-3 shows the summer peak demand impact by DSM program. The demand impact grows from 0.5% of forecasted peak demand in 2007 to 8.0% of peak demand in 2026.

Figure 4-4 shows the system annual energy impacts of the cost-effective demand-side management programs and Figure 4-5 provides the annual energy impact by program. The energy impact increases from 0.1% of forecasted energy requirements in 2007 to 5.4% in 2026.

DSM Energy Impact

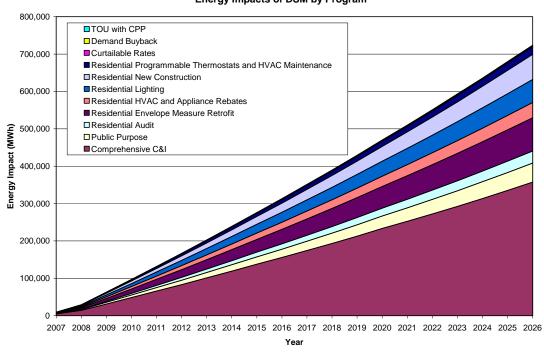

Figure 4-5 Energy Impacts of DSM by Program

4.2.2 Wind Generation Power Purchase Agreements and Ownership

Wind generation was analyzed in a manner similar to the demand-side management programs because of the methodology of modeling non-dispatchable resources in the MIDAS Gold model. The costs of wind PPAs and generation ownership were modeled based on recent proposals from wind project developers. Neither wind option was cost effective when modeled against the dispatchable power supply resource options. However, the wind PPA was only marginally higher cost and new wind generation proposals will be requested when ANM issues a request for power supply proposals in the spring of 2006.

4.3 SUMMARY OF ALTERNATIVE RESOURCE PLANS WITH DSM

The Alternative Resource Plans (ARPs) developed for Aquila Networks - Missouri as a result of the resource integration process described above are based on the Commission's required planning objective of minimizing utility costs (revenue requirements) on a present value basis at the utility's cost of capital of 7.97% over the 20-year planning horizon (2007-2026).

Each ARP assumes that a different mix of generation types is available or constrained by environmental limits. The MIDAS capacity expansion module was used to determine the least cost capacity expansion plan using the limitations

specific to each plan. A description of the ARPs is included in the following paragraphs.

4.3.1 No New Coal Generation

The "No New Coal Generation" ARP assumes that PPAs are available through 2012 to meet all capacity requirements and also assumes no coal-fired generation additions are available during the study period. The financial and operating data output from the modeling of this plan are included as Appendix 4-B.

4.3.2 Power Purchase Agreements Through 2012

The "PPAs Through 2012" ARP assumes that PPAs are available through 2012 and no other generation types are excluded during the entire study period. This plan was the least-cost supply-side only plan and remains the least cost plan with the integration of demand-side management programs. The financial and operating data output from the modeling of this plan are included as Appendix 4-C.

4.3.3 Power Purchase Agreements Through 2009

The "PPAs Through 2009" ARP assumes that PPAs are available through 2009 and no other generation types are excluded during the entire study period. The financial and operating data output from the modeling of this plan are included as Appendix 4-D.

4.3.4 No New Gas Generation

The "No New Gas Generation" ARP assumes that PPAs are available through 2012 and also assumes no gas-fired generation additions are available during the study period. The financial and operating data output from the modeling of this plan are included as Appendix 4-E.

4.3.5 Green

The "Green" ARP assumes that PPAs are available through 2012 and also assumes that Aquila will self-impose a CO_2 emissions limit of 6.5 million tons beginning in 2015. This limit is equal to ANM's CO_2 emissions level in the year 2000. The generation additions in this plan are the least cost alternatives that allow ANM to meet the CO_2 limit. The financial and operating data output from the modeling of this plan are included as Appendix 4-F.

4.4 COMPARISON OF ALTERNATIVE RESOURCE PLANS

4.4.1 Generation Additions for Alternative Resource Plans

Table 4-3 summarizes the generation additions and net present value of revenue requirements (NPVRR) for each of the ARPs with DSM integrated. The table shows that the "PPAs through 2012" alternative resource plan is the lowest cost

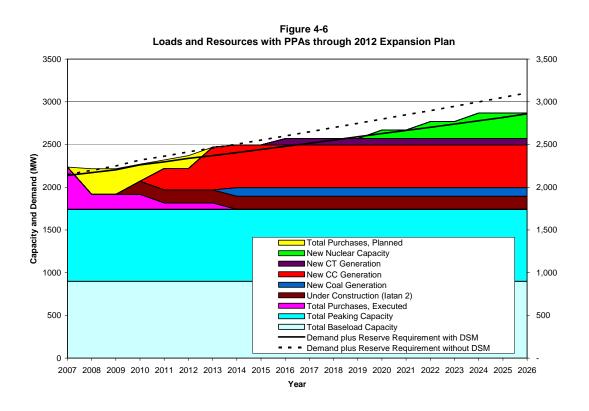

among these six ARPs when comparing 20-year net present value of revenue requirements and the "No Coal" ARP is the lowest cost using a 10-year NPVRR. All references to PPAs in Table 4-3 represent the total PPA resource in that year. The PPA amounts are not additive from one year to the next.

Table 4-3
Generation Additions and Capacity Purchases for Alternative Resource Plans

All plans show a large increase in revenue requirements and the resulting rates in the year 2010 due to the additions of latan 2 and planned environmental projects. The decrease in revenue requirements in the year 2009 is largely the result of forecasted natural gas price decreases which leads to lower forecasted spot market energy prices. The No Coal and PPA alternative resource plans do not vary significantly in the levelized rates as shown in Table 4-5 with all three plans within 0.5% of each other.

The pretax interest coverage ratio (including allowance for funds used during construction (AFUDC)), ratio of total debt to total capital, and ratio of net cash flow to capital expenditures for the ARPs are included in Appendix 4-G.

4.4.3 Environmental Comparison of ARPs

Table 4-6 shows the annual emission levels of NOx, SO₂, Hg, and CO₂ for each of the ARPs and Table 4-7 shows the annual emission cost comparison. The annual costs are largely driven by the forecast of CO₂ emissions costs as described in Part 2 of the IRP.

4.3 CONCLUSIONS

ANM has identified six Alternative Resource Plans which attempt to meet the objective of minimizing revenue requirements while addressing other important planning objectives. The No Coal, PPAs through 2009, and PPAs through 2012 ARPs are very similar from a financial and emissions standpoint. All of these plans will be further evaluated in Part 5 – Risk Analysis and Strategy Selection.
