2007 INTEGRATED RESOURCE PLAN (IRP) OVERVIEW

The key results of the Integrated Resource Plan can be summarized into the items in the following paragraphs:

- **Load Forecast and Demand-Side Management (DSM)**

Peak Demand is projected to grow at an average annual rate of 2.0% for the next twenty years.

The cost effective DSM programs included in the IRP would reduce demand growth to less than 1.6% per year. This DSM impact effectively eliminates the need for 218 MW of capacity over the next twenty years and reduces the growth rate of peak demand by more than twenty percent.

- **Power Supply**

Preferred Plan of Resource Additions

225 MW of Combustion Turbines in 2010

250 MW of Combined Cycle in 2013

200 MW of Coal Generation Participation in 2017

300 MW of Nuclear Generation Participation in 2022

It should be noted that Aquila would only be a participant in a larger nuclear generating project similar to its participation in Iatan 2. At this time our current cost estimates of nuclear construction and carbon emissions make nuclear power the most cost-effective resource to meet power supply demands in the 2020 to 2026 time frame. A combination of coal, coal gasification, and gas-fired resources could replace the nuclear additions for a small cost increase if participation in nuclear generation is not available or if cost estimates change.

- **Wind Power**

Aquila currently has 60 MW of wind generation and continues to pursue opportunities to add more. At this time our offers for wind power are not cost effective, however, Aquila will be issuing a Request for Proposals (RFP) for power supply including renewable resources in the next month.

The Integrated Resource Plan developed for Aquila Networks – Missouri provides the framework for the planning horizon subject to the results of the upcoming RFP. The planning for generating resource additions is a continuous and iterative process. The following discusses in more detail the key findings of the IRP.

ES.1 LOAD FORECAST SUMMARY

Energy forecasts for residential, commercial, industrial, other, and wholesale classes were developed for the Aquila Networks - Missouri resource plan update in May 2006. Regional economic growth for Aquila's Missouri electric utility service areas (Missouri Public Service (MPS) and St. Joseph Light & Power (SJLP)) were used to forecast long-term growth in energy sales.

Actual summer peak demand for Aquila Networks - Missouri (MPS and SJLP combined) of 1,967 MW occurred at hour 18 on 8/9/06. MPS actual summer peak demand on 8/9/06 hour 18 was 1,521 MW. SJLP actual summer peak demand on 8/9/06 hour 18 was 446 MW.

Table ES-1 provides a load forecast summary of the Base-Case for Aquila Networks-Missouri utilities overall (MPS and SJLP) without the impacts of demand-side management which will be discussed later in the Executive Summary. Energy growth is forecast in the Base-Case to average 2.5% annually during 2006-2025. Coincident summer peak demand growth is forecast to average 2.0% annually during 2006-2025. Annual coincident system load factor in 2006 is forecast at 50.2% increasing to 55.4% by 2025.

Table ES-1
Load Forecast Summary (Base-Case)
(Annual Energy GWh and Summer Peak Demand MW)

| Year | Base-MPS EnergyGWh | Base-SJLP EnergyGWh | Base-MO EnergyGWh | Base-MPS SPeakMW | Base-SJLP SPeakMW | Base-MO SPeakMW | Base-MPS LF% | Base-SJLP LF% | Base-MO LF% |

| 2006-25 | 2.8% | 1.5% | 2.5% | 2.2% | 1.3% | 2.0% | 0.3% | 0.1% | 0.3% |

Table ES-2 provides a load forecast summary of the High-Case and Low-Case economic growth scenarios for Aquila Networks - Missouri utilities overall (MPS and SJLP). Energy growth is forecast in the High-case to average 2.7% annually and 2.4% in the Low-Case during 2006-2025. Summer peak demand growth is forecast in the High-Case to average 2.1% annually and 1.9% in the Low-Case during 2006-2025. Annual coincident system load factor in the High-Case in 2006 is forecast at 50.2% increasing to 56.1% by 2025, and in the Low-Case increasing to 54.8%.

Table ES-3 provides a load and resource forecast for ANM from 2007-2016, the first ten years of the planning horizon. Recent power purchase agreements (PPAs) entered into by ANM for 300 MW of summer capacity will meet reserve margin requirements for the summer of 2007.

ES.2 PROBABLE ENVIRONMENTAL COSTS

Probable environmental costs were estimated for both existing resources and potential new supply options, based on estimates of specific emission rates for each supply resource and the most likely cost of expected mitigation. These probable environmental costs were utilized in screening supply-side resource options, and estimating avoided costs for evaluating demand-side resource options.

ANM utilized values for environmental emissions costs of SO₂, Hg, and NO_x from the “Study of Emission Reduction Strategies to Comply with CAIR and CAMR” prepared for ANM by Sargent & Lundy on May 9, 2006. A copy of this study is included in Appendix 2-D. The equipment cost estimates in the study were updated in December, 2006 after bids for NO_x controls were obtained. The “High” and “Low” emissions cost forecasts from this study were projected to be the future price range of emissions allowances. The “Probable” emission cost forecasts were calculated to be the average of the “high” and “low” forecasts based on our estimation of the equal probability of these forecasts.

The estimated costs of CO₂ emissions were taken from the Synapse Energy Economics, Inc. paper titled “Climate Change and Power: Carbon Dioxide Emissions

Costs and Electricity Resource Planning” dated June 8, 2006 and included as Appendix 2-E. The “Synapse Mid Case” forecast was chosen as the “Probable” forecast for the purposes of the IRP. As discussed in the Risk Analysis section of the IRP, the CO₂ cost forecast is a significant driver in the selection of future generating resources.

Table ES-4 summarizes the range of environmental costs from these studies for each emission.

Table ES-4
Environmental Costs Utilized in the 2007 ANM Integrated Resource Plan

| Year | SO ₂ (\$/ton) | | | Ozone Season NO _x (\$/ton) | | | Annual NO _x (\$/ton) | | | Mercury (\$/ounce) | | | Mercury (\$/lb) | | | CO ₂ (2005 \$/short ton) | | |

High and low forecasts from the Sargent & Lundy study of 5/9/06, except for the CO₂ forecast which is from the Synapse Energy Economics paper "Climate Change and Power: Carbon Dioxide Emissions Costs and Electricity Resource Planning," dated 6/8/06.

The probable environmental costs for these emissions as shown in Table ES-4 are the estimated mitigation costs for each pollutant for purposes of the supply-side and demand-side resource analysis. These environmental costs were used in the ANM Integrated Resource Plan for screening supply-side resources, and determining the optimal supply-side only plan for purposes of calculating avoided costs, which were, in turn, used to screen demand-side resources.

ES.3 SUPPLY-SIDE SCREENING ANALYSIS

From the Supply-Side Screening Analysis, it is shown that the proven technologies based on coal-fueled systems and combustion turbine systems prove to be the leaders in cost effective supply sources. A full list of generating resources carried forward into the resource planning process and the operating and cost data used in the production cost modeling are included in Appendix 2-G. It should be noted that for the generating resources that are typically built with high capacities for economies of scale (nuclear and coal for example), it was assumed that Aquila would not be the lead developer, but would be able to participate in ownership of these units in blocks of 100 MWs. The expected costs of emission control equipment are included in the capital cost estimate as appropriate.

Table ES-5 provides a summary of the fuel uncertainties and the capital and operating cost uncertainties for each of the resource options identified previously are included in Appendix 2-G. All of the probabilities are based on the judgment of decision makers within ANM. Because of recent increases in the cost of labor and construction materials, as evidenced by the price increases for the Iatan 2 project, the project capital costs and fixed O&M costs are more heavily weighted on the high side of our current base estimates.

Table ES-5
Fuel Price Forecast Ranges (\$/mmBtu) (nominal \$)

| Year | Low Sulfur Coal [1] | | | High Sulfur Coal [2] | | | Blended Coal [3] | | | Natural Gas [4] | | |
|-------------|---------------------|--------|--------|----------------------|--------|--------|------------------|--------|--------|-----------------|--------|--------|
| | Low | Base | High | Low | Base | High | Low | Base | High | Low | Base | High |

ES.4 DEMAND-SIDE MANAGEMENT

ES.4.1 Demand-Side Planning Process

Aquila has analyzed a wide variety of demand side management (DSM) programs in support of the IRP process. The company has retained the services of Quantec, LLC to assist with the identification and evaluation of various DSM initiatives. The scope, methodology, and results of this study are detailed in Quantec's final report and are included as Appendix 3-B to this document.

ES.4.2 Energy Efficiency Results

Technical energy efficiency (EE) program potentials in the residential and commercial sectors were based on an analysis of 130 unique electric measures. Six residential segments (existing single-family, manufactured, and multi-family; and new-construction single-family, manufactured, and multi-family) and 20 commercial segments (ten building types within each of the existing and new structure segments) were considered. Since many energy-efficiency measures are applied to multiple segments and building types, a total of 1,719 electric measure/structure combinations were included in the analysis. All major end uses in all 20 major industrial segments in Aquila's Missouri service areas were analyzed.

An accurate assessment of achievable EE potentials represented an important objective of this study. In addition, considering realistic market penetration rates, the achievable DSM potential analyses aggregated the estimates into "blocks" of available energy-

efficiency resources that were sizable enough to compare to and evaluate against supply options on a balanced and consistent basis. The blocks, in this case, were the proposed Aquila programs:

- Comprehensive Commercial and Industrial
- Public Purpose
- Residential Audit
- Residential Envelope Measure Retrofit
- Residential HVAC and Appliance Rebates
- Residential Lighting
- Residential New Construction
- Residential Programmable Thermostats and HVAC

ES.4.3 Demand Response Results

The results of the assessment of various demand-response (DR) strategies indicate that direct load control and critical peak pricing, with respective achievable potentials of 12 MW and 11 MW, offer the largest opportunities for demand-response interventions. Opportunities resulting from curtailment contracts and demand buy-back are expected to be less, estimated at 0.5% and 0.3% of system peak, respectively.

ES.4.4 Program Portfolio Overview

Aquila's DSM programs for Missouri were designed to capture the achievable energy-efficiency and demand-response potential identified above. The portfolio of proposed programs is displayed in Table ES-6.

**Table ES-6
Aquila Proposed Programs**

| Category | Sub-Category (If Applicable) |
|---|--|
| Residential Programs | |
| Residential Lighting | |
| Residential Audits | |
| Thermal Envelope Improvements | |
| HVAC Equipment and Appliances | |
| Programmable Thermostats & HVAC Maintenance | |
| Residential New Construction | |
| Non-Residential Programs | |
| Comprehensive Commercial and Industrial Program | Audits |
| | Custom and Prescriptive Rebates |
| Public Purpose Programs | |
| Low-income Assistance | Weatherization |
| | Energy Education through Community-Based Organizations |
| | Affordable Housing Initiative |
| School-Based Energy Education | |
| Research & Development | |
| Energy Efficiency | |
| Demand Response Programs | |
| Direct Load Control | |
| Curtailable Rates | |
| Demand Buyback | |
| Critical Peak Pricing | |

The projected impacts of the energy-efficiency programs are shown in Table ES-7.

Table ES-7
Energy Efficiency Plan Impacts

| | Incremental Impacts | | Cumulative Impacts | |
|--------|---------------------|------------|--------------------|-------------|
| | kW | kWh | kW | kWh |
| Year 1 | 3,711 | 9,090,062 | 3,711 | 9,090,062 |
| Year 2 | 7,824 | 19,414,689 | 11,535 | 28,504,751 |
| Year 3 | 13,512 | 33,712,997 | 25,048 | 62,217,748 |
| Year 4 | 13,577 | 33,907,729 | 38,625 | 96,125,478 |
| Year 5 | 13,803 | 34,530,618 | 54,428 | 130,656,095 |

Based on the Quantec analysis of DSM programs, the twelve energy efficiency programs and four demand response programs were evaluated against the supply-side resources using the MIDAS Gold production cost model.

ES.5 RESOURCE INTEGRATION

As required by the Commission's rules, the primary objective utilized by ANM in developing the optimal energy plan was minimization of the present value of revenue requirements over the 2007-2026 planning period. In addition to this objective, alternative resource plans (ARPs) were also developed for other important planning objectives, as follows:

- Minimize CO₂ production – The “No New Coal Generation” ARP prohibits the addition of new coal-fired resources and thus lowers the systemwide production of CO₂. The “Green” ARP examines the cost impact of ANM unilaterally setting its own CO₂ emission rate limit at 6.5 million tons per year beginning in 2015, equivalent to the ANM level of CO₂ emissions in the year 2000.
- Minimize dependence on natural gas – The “No New Gas Generation” ARP provides an alternative plan for ANM to not increase its exposure to the volatile natural gas market in the generation of electricity.

ES.5.1 Resource Integration Process

The resource integration process is automated in the MIDAS Gold™ software to comply with the requirement in 4 CSR 240-22.010(2)(A) of the rules. This section of the rules states that the utility shall consider and analyze demand-side efficiency and energy management measures on an equivalent basis with supply-side alternatives in the resource planning process.

ES.5.2 Demand-Side Management Programs

The Demand-Side Management Programs identified in the demand-side management screening analysis were evaluated against the supply-side resources using the MIDAS Gold production cost model. The only DSM program that was not determined to be cost effective was the direct load control (DLC) program. Table ES-8 provides an overview of the DSM program impacts on ANM-system demand and energy along with the total costs of the cost-effective programs.

Table ES-8
Impact of Demand-Side Management Programs

| Year | Energy Efficiency | | | Demand Response | | | Total | | |
|------|---|------------------------|-----------------|---|------------------------|-----------------|--|------------------------|-----------------|
| | Total Non-Coincident Demand Impact (MW) | Energy Reduction (MWh) | Total Cost (\$) | Total Non-Coincident Demand Impact (MW) | Energy Reduction (MWh) | Total Cost (\$) | Total Coincident Peak Demand Impact (MW) [1] | Energy Reduction (MWh) | Total Cost (\$) |
| 2007 | 3.7 | 9,050 | 4,152,436 | 7.8 | 480 | 2,422,580 | 10.2 | 9,530 | 6,575,016 |
| 2008 | 11.5 | 28,390 | 7,510,036 | 15.7 | 950 | 1,613,628 | 23.1 | 29,340 | 9,123,663 |
| 2009 | 25.0 | 62,020 | 11,692,454 | 23.5 | 1,100 | 1,761,812 | 39.5 | 63,120 | 13,454,267 |
| 2010 | 38.6 | 95,750 | 11,752,850 | 24.1 | 1,490 | 967,394 | 48.8 | 97,240 | 12,720,244 |
| 2011 | 52.4 | 130,040 | 12,164,206 | 24.8 | 1,700 | 1,000,302 | 58.2 | 131,740 | 13,164,507 |
| 2012 | 66.4 | 164,830 | 12,483,859 | 25.4 | 1,970 | 1,041,767 | 67.8 | 166,800 | 13,525,627 |
| 2013 | 80.6 | 200,560 | 12,854,347 | 26.0 | 2,190 | 1,084,073 | 77.4 | 202,750 | 13,938,420 |
| 2014 | 95.0 | 236,720 | 13,485,491 | 26.7 | 2,410 | 1,128,192 | 87.2 | 239,130 | 14,613,683 |
| 2015 | 109.5 | 273,580 | 14,207,839 | 27.4 | 2,610 | 1,174,326 | 97.2 | 276,190 | 15,382,165 |
| 2016 | 124.3 | 310,360 | 14,969,457 | 28.0 | 2,920 | 1,222,249 | 107.3 | 313,280 | 16,191,706 |
| 2017 | 139.3 | 348,150 | 15,692,767 | 28.8 | 3,190 | 1,273,755 | 117.5 | 351,340 | 16,966,522 |
| 2018 | 154.5 | 386,530 | 16,412,567 | 29.5 | 3,150 | 1,327,139 | 127.9 | 389,680 | 17,739,706 |
| 2019 | 170.0 | 425,920 | 17,355,025 | 30.2 | 3,480 | 1,382,230 | 138.5 | 429,400 | 18,737,254 |
| 2020 | 185.7 | 466,470 | 17,852,616 | 31.0 | 3,830 | 1,441,090 | 149.3 | 470,300 | 19,293,707 |
| 2021 | 201.6 | 506,370 | 18,679,284 | 31.8 | 3,660 | 1,501,429 | 160.3 | 510,030 | 20,180,714 |
| 2022 | 217.9 | 547,170 | 19,991,271 | 32.6 | 3,870 | 1,565,525 | 171.4 | 551,040 | 21,556,796 |
| 2023 | 234.5 | 589,060 | 21,544,204 | 33.4 | 4,400 | 1,632,852 | 182.8 | 593,460 | 23,177,057 |
| 2024 | 251.3 | 631,980 | 23,050,903 | 34.3 | 3,650 | 1,703,235 | 194.5 | 635,630 | 24,754,138 |
| 2025 | 268.6 | 675,950 | 23,739,358 | 35.2 | 3,900 | 1,777,352 | 206.4 | 679,850 | 25,516,710 |
| 2026 | 285.7 | 719,950 | 24,051,420 | 36.1 | 3,840 | 1,854,635 | 218.3 | 723,790 | 25,906,055 |

[1] The sum of Energy Efficiency and Demand Response Demand Impact do not equal the total peak reduction due to non-coincidence of the program impacts.

The summer peak demand impacts of the cost-effective demand-side management programs represent an average annual peak demand growth reduction from 2.0% to 1.6% over the study period. The summer peak demand impact grows from 0.5% of forecasted peak demand in 2007 to 8.0% of peak demand in 2026. The energy impact increases from 0.1% of forecasted energy requirements in 2007 to 5.4% in 2026.

ES.5.3 Summary of Alternative Resource Plans with DSM

The Alternative Resource Plans (ARPs) developed for Aquila Networks - Missouri as a result of the resource integration process described above are based on the Commission's required planning objective of minimizing utility costs (revenue requirements) on a present value basis at the utility's cost of capital of 7.97% over the 20-year planning horizon (2007-2026).

Each ARP assumes that a different mix of generation types is available or constrained by environmental limits. The MIDAS capacity expansion module was used to determine the least cost capacity expansion plan using the limitations specific to each plan. A description of the ARPs is included in the following paragraphs.

ES.5.3.1 No New Coal Generation

The "No New Coal Generation" ARP assumes that PPAs are available through 2012 to meet all capacity requirements and also assumes no coal-fired generation additions are available during the study period. The financial and operating data output from the modeling of this plan are included as Appendix 4-B.

ES.5.3.2 Power Purchase Agreements Through 2012

The "PPAs Through 2012" ARP assumes that PPAs are available through 2012 and no other generation types are excluded during the entire study period. This plan was the least-cost supply-side only plan and remains the least cost plan with the integration of demand-side management programs. The financial and operating data output from the modeling of this plan are included as Appendix 4-C.

ES.5.3.3 Power Purchase Agreements Through 2009

The "PPAs Through 2009" ARP assumes that PPAs are available through 2009 and no other generation types are excluded during the entire study period. The financial and operating data output from the modeling of this plan are included as Appendix 4-D.

ES.5.3.4 No New Gas Generation

The "No New Gas Generation" ARP assumes that PPAs are available through 2012 and also assumes no gas-fired generation additions are available during the study period. The financial and operating data output from the modeling of this plan are included as Appendix 4-E.

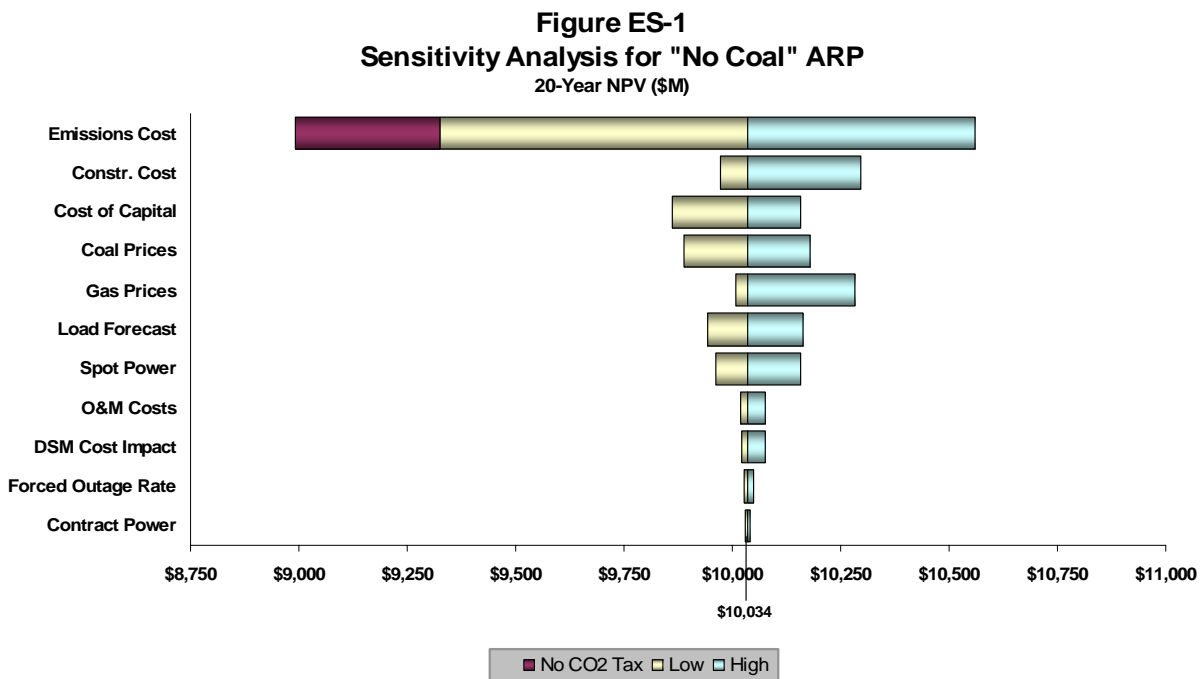

ES.5.3.5 Green

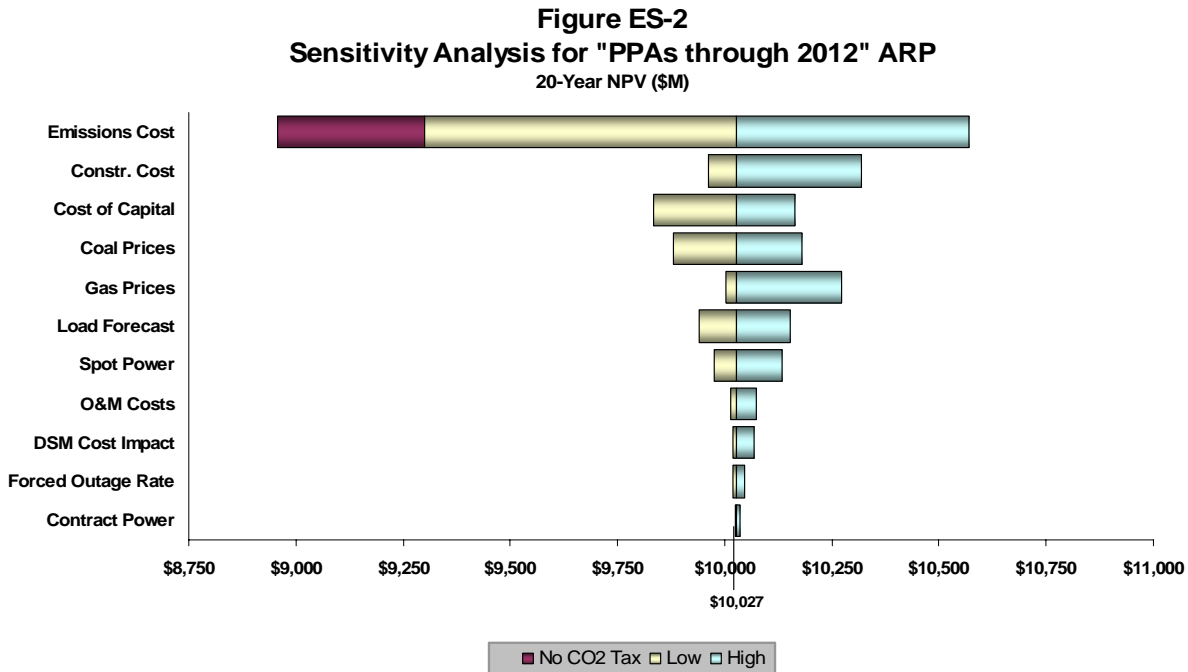

The "Green" ARP assumes that PPAs are available through 2012 and also assumes that Aquila will self-impose a CO₂ emissions limit of 6.5 million tons beginning in 2015. This limit is equal to ANM's CO₂ emissions level in the year 2000. The generation additions in this plan are the least cost alternatives that allow ANM to meet the CO₂ limit. The financial and operating data output from the modeling of this plan are included as Appendix 4-F.

ES.6 SENSITIVITY ANALYSIS

This subsection presents the results of the sensitivity analysis conducted in MIDAS Gold using the alternative resource plans under the objective of minimization of revenue requirements with probable environmental costs. The high and low cases were based on the potential values of the critical variables. Optimal plans were not developed for each variation of the key variables and only the sensitivity of the alternative resource plans to changes in the key variables was analyzed.

Figures ES-1 and ES-2 present the results of the sensitivity analysis for the ARPs with the lowest 20-year net present value of revenue requirements (NPVRR). The figures show the low and high case effects of chance variables on the alternative resource plans. The data referenced in these figures can be found in Appendix 5-B.

The variables that consistently exhibited the most downside risk among the ARPs were:

- Probable Environmental Costs
- Cost of Capital
- Costs of Construction of New Generation Options
- Gas Prices

All of the alternative resource plans are more sensitive to the effect of environmental costs (particularly CO₂) than any other variable.

ES.7 PREFERRED PLAN SELECTION AND COMPARISON TO ALTERNATIVE RESOURCE PLANS

ES.7.1 Introduction

This section presents the preferred resource strategy for Aquila Networks - Missouri and the required implementation plan to acquire these resources. As required by the electric utility planning rules, ANM files the preferred plan as the one with NPVRR minimization with probable environmental costs as the primary objective.

ES.7.2 Preferred Resource Plan Selection

The preferred plan is a combination of the features of several of the ARPs. Similar to the "PPAs through 2009" plan, 225 MW of combustion turbine capacity is added in

2010. The second unit addition is a 250 MW combined cycle unit addition which was included in several of the ARPs. In the preferred plan this unit is installed in 2013. A 200 MW coal-fired generation participation is included in 2017. The final resource addition is 300 MW of nuclear capacity participation in 2022. This is a combination of the multiple nuclear resource additions identified in the other ARPs from 2020 to 2025. Table ES-9 provides the resource additions for the preferred plan which is also the least cost plan considering 20- and 10-year net present values of revenue requirements. Several other low-cost plans are included for comparison purposes. All references to PPAs in Table ES-9 represent the total PPA resource in that year. The PPA amounts are not additive from one year to the next.

Table ES-9
Generation Additions and Capacity Purchases for Alternative Resource Plans

| Alternative Resource Plans | | | | |
|----------------------------|---------------------------------|---------------------------------|---------------------------------|---------------------------------|
| Year | No Coal | PPAs through 2012 | PPAs through 2009 | Least Cost/Preferred |
| 2007 | | | | |
| 2008 | 300 MW PPA | 300 MW PPA | 300 MW PPA | 300 MW PPA |
| 2009 | 300 MW PPA | 300 MW PPA | 300 MW PPA | 300 MW PPA |
| 2010 | 200 MW PPA | 200 MW PPA | 225 MW CT | 225 MW CT |

Figure ES-3 is a plot of the loads and resources for the Preferred Expansion Plan including the resources outlined above and the addition of capacity from Iatan 2.

**Figure ES-3
Loads and Resources with Preferred Expansion Plan**

This preferred plan accomplishes several other objectives while remaining the lowest cost plan. The CT addition in 2010 reduces the reliance on large near-term power purchase agreements. The overall diversity of 200 MW of coal generation, 225 MW of peaking combustion turbines, and 250 MW of combined cycle reduces ANM's natural gas fuel supply risk and dependence on spot market energy purchases. By 2013, we expect certain high efficiency gas technologies to have matured. These include the General Electric LMS100 and Siemens Super Peaker. These technologies promise to combine the best features of peaking and combined cycle units but have limited operations at this time. Finally, the preferred plan minimizes the overlap of 2010 and 2013 construction schedules.

ES.7.3 Financial Analysis of Preferred Plan

This section provides key shareholder value performance measures for the Preferred Resource Plan. Table ES-10 shows the annual revenue requirements for the preferred plan with several of the lower cost ARPs provided for comparison. Table ES-11 shows the annual average rates (cents/kWh) including the levelized rates over the study period.

Table ES-10
Revenue Requirement Comparison

| | No Coal | | PPAs through 2012 | | PPAs through 2009 | | Preferred Plan | |

All plans show a large increase in revenue requirements and the resulting rates in the year 2010 due to the additions of latan 2 and planned environmental projects. The decrease in revenue requirements in the year 2009 is largely the result of forecasted natural gas price decreases which leads to lower forecasted spot market energy prices. The preferred plan has the lowest levelized rates over the 20-year planning horizon as shown in Table ES-11.

ES.7.4 Environmental Analysis of Preferred Plan

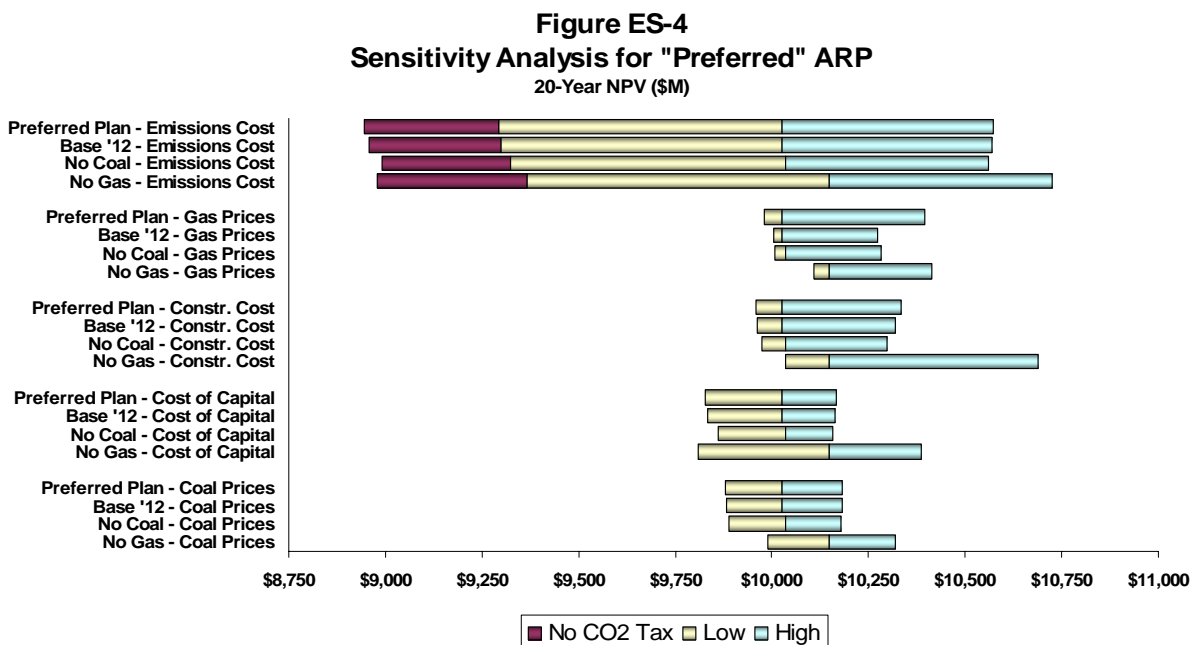

Table ES-12 shows the annual emission levels of NO_x, SO₂, Hg, and CO₂ for the preferred plan. The annual emissions costs are largely driven by the forecast of CO₂ emissions costs as described in Part 2 of the IRP.

Table ES-12
Emission Level Comparison

| Year | No Coal | | | | PPAs through 2009 | | | | PPAs through 2012 | | | | Preferred Plan | | | |
|------|---------------------------|---------------------------|-------------|---------------------------|---------------------------|---------------------------|-------------|---------------------------|---------------------------|---------------------------|-------------|---------------------------|---------------------------|---------------------------|-------------|---------------------------|
| | NO _x (tons) | SO ₂ (tons) | Hg (lbs) | CO ₂ (tons) | NO _x (tons) | SO ₂ (tons) | Hg (lbs) | CO ₂ (tons) | NO _x (tons) | SO ₂ (tons) | Hg (lbs) | CO ₂ (tons) | NO _x (tons) | SO ₂ (tons) | Hg (lbs) | CO ₂ (tons) |

ES.7.5 Sensitivity Analysis of Key Variables

The sensitivity analysis of key variables on the preferred plan and the other lowest cost ARPs is shown in Figure ES-4. The sensitivities of the preferred plan are very similar to the “PPAs through 2012” and “No Coal” expansion plans because of the similarity of resource additions. A more pronounced difference is seen between the preferred and “No Gas” plans with the “No Gas” plan having significantly higher risk associated with emissions costs, construction costs, and cost of money.

ES.7.6 Preferred Plan Alternatives and Flexibility

The integrated resource analysis produced not only a preferred plan, but also a substantial insight into possible alternative supply-side resource opportunities. ANM will embark in the direction of the preferred plan but attempt to maintain and enhance the flexibility to take advantage of resource opportunities that may develop. This subsection will expand upon the inherent flexibility available in the preferred plan.

The integrated analysis was performed considering an objective to minimize utility revenue requirements. This analysis indicated that the upcoming resource decision between combustion turbines and a combined cycle unit was only marginally different in cost impact. The final cost estimates of these technologies and the costs of power purchases (resulting from the Request for Proposals (RFP) to be issued in February 2007) will be the final determination in the ultimate preferred resource plan. In addition,

because the current offers for wind generation were marginally not cost effective, the bids received for wind power in the upcoming RFP may be cost-effective and may alter the preferred plan.

The choice of combustion turbines in 2010 provides contingency benefits for natural gas fuel supply issues and purchase power availability. A significant reduction of the risk of gas supply issues during peak generating periods can be realized by making the combustion turbines dual-fuel capable. In addition, the combustion turbines reduce the dependence on the price and availability of PPAs in 2010.

The preferred plan utilizes 200 MW of new coal-fired generating capacity in 2017. This assumes that ANM will be able to purchase a 200 MW portion of a larger coal-fired resource. If this opportunity is not available or not available at a cost-effective price ANM may be able to replace the planned resource with a 200 MW fluidized bed unit at one of its existing sites to maintain the fuel diversity provided by a coal-fired resource addition.

Similarly the preferred plan calls for ANM to acquire 300 MW of nuclear generation participation in 2022. This opportunity may not be available to ANM. Even with the carbon tax that was included in the probable environmental costs, the inclusion of nuclear generation over coal-fired generation reduces the 20-year NPV by only a marginal amount.

Significant changes could occur during the next two years due to: capital costs of generation, fuel prices, load growth, and new generation technologies. Therefore, ANM could switch the later resources from the coal and nuclear resource participation to new turbine technologies, integrated gasification combined cycle units, and improved renewable resources, or a combination of these resources. Although these resources are not listed explicitly as part of the preferred plan, they are integral elements of contingency options available in the preferred strategy.

ES.8 IMPLEMENTATION AND RESOURCE ACQUISITION STRATEGY

ES.8.1 Demand-Side Implementation

All of the cost-effective demand-side programs will begin to be implemented upon approval of the programs and establishment of an appropriate cost recovery mechanism by the Missouri Public Service Commission. Various implementation strategies will be investigated with input from Quantec.

The initial planning strategy is to promote customer awareness through brochures, bill inserts and other printed material; trade ally meetings; a program information telephone line; and through the Company web-site. Other options will be evaluated to promote energy-efficiency among customers including: (1) radio and television advertisements, (2) newspapers, magazines and billboards, (3) telemarketing, and (4) other innovative

marketing methods. The demand-side programs will be implemented upon approval of the programs and establishment of an appropriate cost recovery mechanism by the Missouri Public Service Commission. Evaluation, measurement and verification of the programs will begin during 2008.

ES.8.2 Supply-Side Implementation and Contingency Monitoring

The preferred plan includes the addition of the following four supply-side resources over the planning horizon 2007-2026.

- 225 MW Combustion Turbine Addition in 2010
- 250 MW Combined Cycle Addition in 2013
- 200 MW Coal Participation in 2017
- 300 MW Nuclear Participation in 2022

ANM will be receiving detailed cost estimates of combustion turbine and combined cycle technologies from vendors in the next few months. In addition, ANM will be issuing an RFP for PPAs and wind generation PPAs in February, 2007. Finally, ANM will also be evaluating the results of the brownfield site study being performed by Black & Veatch to determine the potential for utilizing existing sites for new generation and the potential need for unit retirements.

The ANM electric planning group will be monitoring the emissions costs and fuel prices and updating the load forecasts to ensure that there is an ability to evaluate any contingency and develop additional strategies to respond to extreme scenarios.

In addition, ANM will undertake the following activities in the 2008 through 2012 period:

- Monitor the development of CO₂ emissions reduction legislation.
- Continue discussions to renew purchase power contracts that currently expire in 2011 and 2014.
- Pursue discussions with area utilities and independent power developers to determine the potential for unit participation in either coal or nuclear generating units in the 2015-2026 timeframe.
- Continue to evaluate the viability of renewable generation technology options in ANM service territory.

All of the above activities will facilitate the consideration of different types of supply resources to meet customer demand in the 2008-2026 timeframe.
