DIRECT TESTIMONY
OF
TIMOTHY D. FINNELL
CASE NO. ER-2008-____

I. INTRODUCTION

Q. Please state your name and business address.

A Timothy D Finnell, Ameren Services Company (“Ameren Services”), One Ameren Plaza, 1901 Chouteau Avenue, St Louis, Missouri 63103

Q. What is your position with Ameren Services?

A I am a Managing Supervisor, Operations Analysis in the Corporate Planning Function of Ameren Services Ameren Services provides corporate, administrative and technical support for Ameren Corporation and its affiliates

Q. Please describe your educational background and work experience, and the duties of your position.

A I received my Bachelor of Science Degree in Industrial Engineering from the University of Missouri-Columbia in May 1973 I received my Master of Science Degree in Engineering Management from the University of Missouri-Rolla in May 1978 My duties include developing fuel budgets, reviewing and updating economic dispatch parameters for the generating units owned by Ameren Corporation subsidiaries, including Union Electric Company d/b/a AmerenUE (“AmerenUE”), providing power plant project justification studies, and performing other special studies

I joined the Operations Analysis group in 1978 as an engineer In that capacity, I was responsible for updating the computer code of the System Simulation

1 Program, which was the production costing model used by Union Electric Company (“UE”)
2 at that time I also prepared the UE fuel budget, performed economic studies for power plant
3 projects, and prepared production cost modeling studies for UE rate cases since 1978 I was
4 promoted to Supervising Engineer of the Operations Analysis work group in 1985 I became
5 an Ameren Services employee in 1998, when UE and Central Illinois Public Service
6 Company merged My title was changed to Managing Supervisor in February 2008

7 **II. PURPOSE AND SUMMARY OF TESTIMONY**

8 **Q. What is the purpose of your testimony in this proceeding?**

9 A The purpose of my testimony is to sponsor the determination of a normalized
10 level of net fuel costs, which was used by AmerenUE witness Gary S Weiss in determining
11 AmerenUE’s revenue requirement for this case Net fuel costs consist of nuclear fuel, coal,
12 oil, and natural gas costs associated with producing electricity from the AmerenUE
13 generation fleet, plus the variable component of purchase power, less the energy revenues
14 from off-system sales¹ I also address a minimum filing requirement associated with
15 AmerenUE’s request for a fuel adjustment clause (“FAC”), specifically, the requirement
16 found at 4 CSR 240-3 161(2)(O)

17 An executive summary of my testimony is attached hereto as Attachment A

¹ “Net fuel costs” as used in my testimony are slightly different than the “net base fuel costs” (“NBFC”) discussed in the direct testimony of AmerenUE witness Martin J Lyons, Jr , and as defined in the Company’s proposed FAC tariff This is because NBFC also includes costs that are not the product of my production cost modeling but which are part of total fuel and purchased power expense included in Mr Weiss’ revenue requirement, principally as follows fixed gas supply costs, credits against the cost of nuclear fuel from Westinghouse arising from a prior settlement of a nuclear fuel contract dispute, Day 2 energy market expenses from the Midwest Independent Transmission System Operator, Inc (“MISO”), excluding administrative fees, MISO Day 2 congestion charges, MISO Day 2 revenues, and capacity sales revenues

1 **Q. Please summarize your testimony and conclusions.**

2 A The normalized net fuel costs were calculated using the PROSYM production
3 cost model. The major inputs for the production cost model include hourly load data,
4 generating unit operational data, generating unit availability data, fuel costs, off-system
5 market data, and system requirements. The normalized annual net fuel costs are \$290
6 million, which consists of fuel costs of \$678 million and variable purchase power costs of
7 \$55 million, offset by off-system sales revenues of \$443 million.

8 **III. PRODUCTION COST MODELING - GENERALLY**

9 **Q. What is a production cost model?**

10 A. A production cost model is a computer application used to simulate an electric
11 utility's generation system and load obligations. One of the primary uses of a production
12 cost model is to develop production cost estimates used for planning and decision making,
13 including the development of a normalized level of net fuel costs upon which a utility's
14 revenue requirement can be based.

15 **Q. Is the PROSYM model used by Ameren Services a commonly used**
16 **production cost model?**

17 A Yes. PROSYM is a product of Global Energy Decisions ("GED"). The
18 PROSYM production cost model is widely used either directly or indirectly by utilities
19 around the world. By indirectly I mean that the PROSYM logic is used to run numerous
20 other products that GED offers.

21 **Q. How long has Ameren Services been using PROSYM to model**
22 **AmerenUE's system?**

1 A Ameren Services has been using PROSYM to model AmerenUE's system
2 since 1995

3 **Q. How is PROSYM used by Ameren Services?**

4 A PROSYM is operated and maintained by the Operations Analysis Group
5 Some of the most common uses of PROSYM are preparation of the monthly and annual
6 fuel burn projections, support for emissions planning, evaluation of major unit overhaul
7 schedules, evaluation of power plant projects, and support for regulatory requirements such
8 as Federal Energy Regulatory Commission Public Utility Regulatory Policy Act ("PURPA")
9 filings and rate cases such as this one

10 **Q. What are the major inputs to the PROSYM model run used for**
11 **calculating a normalized level of net fuel costs?**

12 A The major inputs include normalized hourly loads, unit availabilities, fuel
13 prices, unit operating characteristics, hourly energy prices, and system requirements

14 **Q. Do different production cost models produce similar results?**

15 A Most models should have similar logic for optimizing generation costs and
16 should produce similar results, all else being equal. However, some models have a higher
17 level of accuracy because, for example, they are able to perform a more detailed optimization
18 for systems like AmerenUE's system with a run of river plant, a stored hydroelectric plant, a
19 pumped storage plant, and reserve requirements. The dispatch of hydroelectric and pumped
20 storage plants is an important part of AmerenUE's generation cost optimization and requires
21 a model that is able to optimize those types of plants. PROSYM is such a model. Our
22 experience with PROSYM indicates that it does a superior job of simulating complex
23 generating systems such as AmerenUE's system

1 **Q. Are there other key issues relating to production cost modeling?**

2 A Yes Another very important issue is how well the model is calibrated to
3 actual results. Model calibration is done by using model inputs that reflect actual (i.e. not
4 normalized) data for a specific time period and comparing the simulated results produced by
5 the model to the actual generation performance for that time period. Production cost model
6 outputs that should be compared to actual data to properly calibrate the model include: unit
7 generation totals for the period being evaluated; hourly unit loadings, unit heat rates, number
8 of hot and cold starts, and off-system sales volumes.

9 **Q. How well is the PROSYM model calibrated?**

10 A The PROSYM model is very well calibrated as demonstrated by the results of
11 a calibration conducted under my supervision which compared actual 2007 generation to
12 model results. For example, the calibrated model results calculated the generating output
13 from AmerenUE to be 50,459,800 megawatt-hours ("MWh"). Actual generation was
14 50,319,199 MWhs, thus the model result was within 1% of the actual generation. Another
15 example of how well the model is calibrated is reflected in the predicted off-system sales
16 produced by the model versus the actual off-system sales for the study period. Those results
17 (10,962,200 MWh from the model versus 10,984,356 MWh actual) were also within 1% of
18 the actual results. Based upon my experience, these results demonstrate the high level of
19 accuracy of the model. Detailed results of the calibration are shown in Schedule TDF-E1.

20 **Q. There appears to be a larger difference between the calibrated model**
21 **combustion turbine generator ("CTG") generation and the actual CTG generation.**
22 **Why is that?**

1 A The calibrated model's annual CTG generation was 714,200 MWh and the
2 actual CTG generation for 2007 was 889,692 MWh, which results in a 25% difference
3 between model generation and actual generation. The CTG generation is influenced by many
4 factors, such as loads, availability of other units, cost of CTG generation, energy market
5 prices, AmerenUE system requirements, transmission considerations, and MISO operations.
6 Since the calibrated model used actual loads, actual unit availabilities, actual operating costs,
7 actual energy market prices, and actual AmerenUE system requirements, I have concluded
8 that transmission considerations and, notably, MISO operations were responsible for the
9 inaccuracy of the model's CTG generation. This conclusion is supported by a review of the
10 monthly variations between modeled and actual CTG generation. For example, in October, a
11 month when little CTG generation is expected, the model calculated 30,900 MWh of CTG
12 generation, yet there was 118,467 MWh of actual CTG generation. In that same month
13 AmerenUE received \$3.3 million of MISO make-whole payments for generation that did not
14 receive adequate revenues (because it was dispatched uneconomically by the MISO). In
15 general, the CTG modeling is not only difficult because of transmission considerations and
16 MISO operations, but it is also very dependent on loads, availability of other units, and
17 market prices.

18 **Q. What must one do to achieve a high level of calibration in modeling a**
19 **utility's generation?**

20 A One must look carefully at the model inputs that could affect the results. For
21 example, if the model's result for generation output is too low compared to actual values
22 there are several items that would need to be reviewed. These items include the analysis of
23 whether (1) the dispatch price is too high, (2) the unit availability factor is too low, (3) the

1 minimum load is too low, (4) the unit start-up costs are incorrect, (5) the minimum up and
2 down times are incorrect, and (6) the off-system sales market is incorrectly modeled

3 **Q. What are the implications of using a less well calibrated model to**
4 **determine revenue requirement in a rate case?**

5 A A poorly calibrated model will inevitably lead to an inaccurate determination
6 of a normalized level of net fuel costs

7 **IV. PRODUCTION COST MODEL INPUTS**

8 **Q. What type of load data is required by PROSYM?**

9 A PROSYM utilizes monthly energy with a historic hourly load pattern The
10 monthly energy reflects AmerenUE kilowatt-hour ("kWh") sales and line losses
11 AmerenUE's normalized sales plus line loss values were provided to me by Mr Weiss
12 For this case, the actual 2007 hourly load pattern is applied to normalized monthly energy
13 and generates a normalized hourly load pattern

14 **Q. What operational data is used by PROSYM?**

15 A Operational data reflects the characteristics of the generating units used to
16 supply the energy for native load customers and to make off-system sales The major
17 operational data includes the unit input/output curve, which calculates the fuel input
18 required for a given level of generator output, the generator minimum load, which is the
19 lowest load level at which a unit normally operates; the maximum load, which is the
20 highest level at which the unit normally operates, and fuel blending. Schedule TDF-E2
21 lists the operational data used for this case

1 **Q. What availability data is used by PROSYM?**

2 A The availability data are categorized as planned outages, unplanned outages
3 and deratings

4 Planned outages are major unit outages that occur at scheduled intervals The
5 length of the scheduled outage depends on the type of work being performed. Planned
6 outage intervals vary due to factors such as type of unit, unplanned outage rates during the
7 maintenance interval, and plant modifications A normalized planned outage length was
8 used for this case, as reflected in Schedule TDF-E3 The length of the planned outages is
9 based on a 6-year average of actual planned outages that occurred between 2002 and 2007,
10 with one exception. The one exception was to remove the 2005 Callaway Nuclear Plant
11 refueling outage from the 6-year average because the 2005 Callaway refueling outage
12 included non-recurring outage work relating to the complete replacement of the steam
13 generators at Callaway In addition to the length of the planned outage, the time period when
14 the planned outage occurs is also important Planned outages are typically scheduled during
15 the spring and fall months when system loads are low Another important factor considered
16 in scheduling planned outages is off-system power prices The planned outage schedule used
17 in modeling AmerenUE's generation with the PROSYM model is shown in Schedule
18 TDF-E4

19 Unplanned outages are short outages when a unit is completely off-line
20 These outages typically last from one to seven days and occur between the planned outages
21 The unplanned outages occur due to operational problems that must be corrected for the unit
22 to operate properly Several examples of unplanned outages are tube leaks, boiler and
23 economizer cleanings, and turbine/generator repairs The unplanned outage rate for this case

1 is based on a 6-year average of unplanned outages that occurred between 2002 and 2007, and
2 is reflected in Schedule TDF-E5

3 Derating occurs when a generating unit cannot reach its maximum output due
4 to operational problems. The magnitude of the derating varies based on the operating issues
5 involved and can result in reduced outputs ranging from 2% to 50% of the maximum unit
6 rating. Several examples of causes of derating include coal mill outages, boiler feed pump
7 outages, and exceeding opacity limits due to precipitator performance problems. The
8 derating rate used in this case is based on a 6-year average of deratings that occurred between
9 2002 and 2007, and is reflected in Schedule TDF-E6

10 **Q. How was the Taum Sauk Plant's availability modeled in PROSYM?**

11 A In order to insulate ratepayers from the financial impact of the unavailability
12 of the Taum Sauk Plant, AmerenUE's system was modeled assuming that Taum Sauk was in
13 service. This lowers the normalized net fuel costs used in this case by capturing the
14 economic benefit of the Taum Sauk Plant to AmerenUE's system. For the test year period,
15 the annual operations of the Taum Sauk Plant resulted in a net fuel cost benefit of \$19.4
16 million, \$17 million of which was determined by the PROSYM model and \$2.4 million of
17 which are capacity sales from the Taum Sauk Plant as addressed in the direct testimony of
18 AmerenUE witness Shawn E. Schukar.

19 **Q. What fuel cost data was used to determine AmerenUE's revenue**
20 **requirements?**

21 A The AmerenUE units burn four types of fuel: nuclear fuel, coal, natural gas,
22 and oil. The nuclear fuel costs are based on the average nuclear fuel cost associated with

1 Callaway Refueling Number 15 which began May 2007 and ends in October 2008 These
2 costs are discussed in detail in the direct testimony of AmerenUE witness Randall J Irwin

3 The coal costs reflect coal and transportation costs based upon coal and
4 transportation prices that became effective as of January 1, 2008, which are discussed in
5 detail in the direct testimony of AmerenUE witness Robert K Neff

6 The natural gas and oil prices are based on the average monthly prices for the
7 period January 1, 2006 to December 31, 2007

8 **Q. What off-system purchase and sales data was used in PROSYM?**

9 A Off-system purchases are power purchases from energy sellers used to meet
10 native load requirements The purchases can be from long-term purchase contracts or short-
11 term economic purchases The only long-term power purchase contract included as an off-
12 system purchase in PROSYM in this case is the purchase of 160 megawatts ("MW") from
13 Arkansas Power & Light Company ("APL") under a purchase power contract entered into
14 with APL in 1991 The price of the APL contract is based on the average contract price for
15 the period January 1, 2007 through December 31, 2007 Short-term economic purchases are
16 used to supply native load when the prices are lower than the cost of generation and the
17 generating unit operating parameters are not violated A violation of the generating unit
18 operating parameters would occur when all units are operating at their minimum load and
19 cannot reduce their output any further In this case, short-term economic purchases are not
20 made even when they are at lower costs than the cost of operating the AmerenUE generating
21 units The price of short-term economic purchases is based on hourly market prices The
22 hourly market prices are based on the average market prices for the period January 1, 2006
23 through December 31, 2007 The volume of short-term economic purchases was assumed to

1 system sales One of the main purposes for spinning reserves is to provide quick response to
2 a system disturbance, such as a generating unit being forced off line UE's current spinning
3 reserve requirement is 43 MW

4 Supplemental reserves can be either spinning or quick start generation that can
5 be made available within 15 minutes after a disturbance The supplemental reserves are not
6 considered stranded MW since they include units that are on line and not fully loaded due to
7 economics as well as units that are off line UE's current supplemental reserve requirement
8 is 63 MW AmerenUE's quick start units include Taum Sauk, Osage, Fairground CTG,
9 Mexico CTG, Moberly CTG, Moreau CTG, Meramec CTG #2, Venice CTG #2, Howard
10 Bend and the Peno Creek CTGs #1- #4

11 **Q. How does the MISO's ancillary service market impact the regulation**
12 **reserves, spinning reserves, and supplemental reserves levels used in the PROSYM**
13 **modeling addressed in this direct testimony?**

14 A The MISO ancillary services market is projected to begin operation
15 September 9, 2008 Thus it was not modeled at this time

16 **Q. Is AmerenUE selling ancillary services to the utility operating**
17 **subsidiaries owned by Ameren Corporation in Illinois?**

18 A Yes, for 2008, AmerenUE is selling 39 MW of spinning reserves and 68 MW
19 of supplemental reserves to Illinois affiliates

20 **Q. Does the PROSYM model include the sales of ancillary services to these**
21 **Illinois utilities?**

22 A No The sales of these ancillary services were not included because they are
23 based on a short-term contract that will end when the MISO ancillary service market begins

1 **Q. Does eliminating the sales of ancillary services to these Illinois utilities**
2 **distort the net fuel and purchase power calculation?**

3 A No The fact that the sale of ancillary services to the Ameren-owned
4 operating utilities in Illinois was eliminated does not distort the net fuel and purchase power
5 costs. The capacity that was held back to provide the spinning reserves was used in the
6 capacity sales calculation discussed by Mr. Schukar in his direct testimony. The lost
7 opportunity costs associated with holding back generation for the Illinois utilities' spinning
8 reserves was replaced by additional off-system sales in the PROSYM model run used to
9 develop the net fuel costs. For example, the PROSYM model has an extra 39 MW of
10 capacity that is made available for off-system sales. The extra sales will be made by the
11 PROSYM model when the cost of the generation is less than the price received from off-
12 system sales.

13 **V. FAC MINIMUM FILING REQUIREMENT**

14 **Q. What is Requirement (O) of 4 CSR 240-3.161(2)?**

15 A Requirement (O) is a list of supply side and demand side resources that the
16 electric utility expects to use to meet its load for the next four true-up years, the expected
17 dispatch of those resources, the reasons why the resources are appropriate for dispatch and
18 the heat rates and fuel types for each supply side resources. Schedule TDF-E8 lists the
19 supply side resources AmerenUE expects to use to meet its load requirements for the periods
20 March 1, 2009 to February 28, 2010; March 1, 2010 to February 29, 2011; March 1, 2011 to
21 February 29, 2012, and March 1, 2012 to February 28, 2013. The table lists the resource
22 name, ownership, primary fuel type, heat rate at full load, and projected generation for the
23 four true-up years. The projected generation for the four true-up years is appropriate because

Direct Testimony of
Timothy D Finnell

1 it was developed from a detailed production cost model run for the true-up years The
2 production cost model used by AmerenUE is the PROSYM production cost model This is
3 the same model that is used by AmerenUE in this case to calculate fuel, purchased power
4 costs and off-system sales revenues The major inputs to the PROSYM production cost
5 model include normalized hourly loads, unit availabilities, fuel prices, unit operating
6 characteristics, hourly energy market prices, and system requirements

7 **Q. Does this complete your direct testimony?**

8 A Yes, it does

EXECUTIVE SUMMARY

Timothy D. Finnell

*Managing Supervisor, Operations Analysis in the Corporate Planning Function of
Ameren Services Company*

The purpose of my testimony is to explain the production cost model used to determine the normalized net fuel costs which consists of fuel costs, the variable component of purchased power costs and off-system sales revenues for this case. I also supply the supply and demand side resources that are expected to serve AmerenUE's load during the four true-up years when the Company's requested fuel adjustment clause would be in effect.

A production cost model is a computer application used to simulate an electric utility's generation system and load obligations. One of the primary uses of a production cost model is to develop production cost estimates used for planning and decision-making. The program I used for my analysis is PROSYM. AmerenUE's experience with this program indicates that it does a superior job of simulating complex generating systems such as AmerenUE's system.

PROSYM utilizes monthly energy with a historic hourly load pattern. The monthly energy reflects AmerenUE kilowatt-hour ("kWh") sales and line losses. The fuel expenses used include the nuclear, coal, oil, and natural gas costs associated with producing electricity from the AmerenUE generation fleet. For purposes of this model, it was presumed that AmerenUE's Taum Sauk plant was available as a generation resource for the entire year. The model also considers normalized hourly loads, unit availabilities, fuel prices, unit operating characteristics, hourly energy market prices, and system requirements.

The normalized net fuel costs for this case are \$290 million, which consists of fuel costs of \$678 million, variable purchase power costs of \$55 million, offset by off-system sales revenues of \$443 million. These results are utilized by AmerenUE witness Gary S Weiss in developing the revenue requirement for AmerenUE.
