SURREBUTTAL TESTIMONY

OF

LEON C. BENDER

THE EMPIRE DISTRICT ELECTRIC COMPANY

CASE NO. ER-2001-299

Jefferson City, Missouri
May, 2001

Surrebuttal Testimony of
Leon C. Bender

1 A. The differences addressed in their rebuttal testimony were the differences in actual
2 test year results, generating units used, fuel prices, amounts and prices of purchased power,
3 capacity contracts used, the dispatch of the units by the model, and transmission constraints

4 Q. Were these differences discussed with EDE at the prehearing?

5 A. Yes. Contrary to the statement by Mr. Beecher in his rebuttal testimony that
6 Staff offered no explanation, these differences were discussed with him and other employees of
7 EDE during the prehearing conference the week of April 16, 2000.

8 Q. Should Staff's production cost model results represent actual test year expenses
9 as alleged in Mr. Beecher's rebuttal testimony?

10 A. No. Actual expenses for the test year are not necessarily representative of
11 expenses for any particular year. Each year is unique in the set of problems that arise because of
12 weather, unit outages, fuel prices, market conditions, and management decisions. Staff
13 normalizes as many of these factors as possible. It seeks to represent a normalized year and not
14 necessarily match any one set of unique circumstances that may have arisen in a particular test
15 year. It is not reasonable to assume the normalized expense would match that of any particular
16 test year's actual result.

17 Q. Did EDE present a production cost model result of actual test year expenses?

18 A. No, the model results presented by EDE to Staff, were that of a looking forward
19 basis. The model results presented by EDE represented what EDE anticipates its system will look
20 like after the State Line Combined Cycle Unit (SLCC) is in service. All but one of the present
21 capacity contracts were not included. EDE's model used futures gas prices rather than actual
22 gas prices, and the energy spot market represented by EDE did not match test year actual data.
23 It also based unit forced outages on anticipated trends in forced outages rather than on actual
24 data. Any comparison of EDE's model expense results and actual test year expenses would be

Surrebuttal Testimony of
Leon C. Bender

1 unwarranted, and any fit that could be found, if such a comparison were to be made, would only
2 be due to coincidence.

3 Q. What were the major differences in the generating units used in the Staff's
4 production cost model?

5 A. These differences are discussed in my direct testimony. As stated in my direct
6 testimony, these differences will be addressed in the true-up process.

7 Q. Has Staff made a production cost model run which more closely reflects the
8 situation that will exist when the SLCC goes in service?

9 A. Yes, Staff has made production cost model runs that include the SLCC and
10 removes the capacity contracts that will expire in the year 2001. One of these runs was used as a
11 basis for the Stipulation and Agreement on fuel and purchase power expense between Staff, EDE
12 and the Office of the Public Counsel.

13 Q. How does the production cost model dispatch the generating units?

14 A. The production cost model schedules generating units to dispatch in a least cost
15 manner based upon the fuel cost and the cost of alternative purchased power. In considering
16 whether to dispatch a unit, the must first be available.

17 Q. Greg Sweet stated in his rebuttal testimony that "the more efficient unit should
18 run more than a less efficient one." Should the production cost model schedule a unit for
19 dispatch simply because it is more efficient than others?

20 A. No. A unit should dispatch before another only if its cost is lower. Cost is
21 determined by multiplying fuel price by heat rate. Among many things, the production cost model
22 considers both the incremental cost of the next unit and the cost of purchased power when
23 dispatching a unit. The incremental cost is the fuel price times the incremental heat rate. A unit
24 with a higher heat rate (low efficiency), if available, will be dispatched before another unit with a

Surrebuttal Testimony of
Leon C. Bender

1 lower heat rate (high efficiency) if the total incremental cost is lower. Even though the heat rate
2 of the SLCC unit is lower than that of even Iatan, Asbury, and all other EDE units, its dispatch cost is
3 still higher than other units and some available purchase power. The dispatch costs (\$/MWH)
4 are listed in my direct testimony in Schedule 1. To fashion a model that would favor running a
5 higher cost unit before other lower cost alternatives, would not be appropriate.

6 Q. In Greg Sweet's and Brad Beecher's rebuttal testimony, they stated that the
7 number of startups in Staff's production cost model was excessive. Have you compared this
8 with actual number of starts?

9 A. No. EDE has not supplied that information. To make a proper comparison,
10 EDE would need to document and supply to Staff information for the last five years on the total
11 number of hot and cold startups on each of its units. The number of startups for SLCC does not
12 yet exist.

13 Q. Have you looked at the factors controlling the number of startups?

14 A. Yes, I have. All the factors, that control the number of startups, were supplied to
15 Staff by EDE. Staff will consider alternative numbers if EDE has mistakenly supplied us with
16 incorrect numbers.

17 Q. Besides economical dispatch, what are these factors that control the number
18 startups a unit will make?

19 A. The factors are listed below along with a brief explanation. Each factor is
20 different for each unit.

21 Ramp Rate – This controls how fast units can start up and is in units of MW per minute.
22 Typically gas turbines can start up and reach full load very quickly while larger coal units start up
23 much slower.

Surrebuttal Testimony of
Leon C. Bender

1 Minimum Uptime – This controls the number of hours a unit must remain on line once it
2 is started up. If a unit is already running and has a minimum uptime of 8 hours the model will
3 continue to run that unit for 8 hours before it can shut it down. A large number in this field
4 would cause the model to continue running this unit rather dispatch another unit.

5 Minimum Downtime – This controls the number of hours a unit must remain shut down
6 once it is shut down by the model. By not allowing the unit to start up once it is shut down, one
7 can control the dispatch and number of startups on a unit.

8 Defined Cold Hours – This field contains the number of down time hours it takes to
9 cause a unit to require a cold start instead of a hot start. When a unit is down for at least this
10 number of hours, the cold start values will be used the next time the unit is started.

11 Q. Are the factors mentioned above the only factors that determine whether or not a
12 unit is started up?

13 A. No, but they are the major factors. A unit will dispatch if it is available and it is
14 economical to do so.

15 Q. Does the number of starts a unit has impact the total expense?

16 A. Yes, each unit has a fixed cost to hot startup and a cold start up and this cost is
17 multiplied by the number of starts and added to the total expense. Therefore, lowering the
18 number of startups a unit performs will lower the total expense.

19 Q. Are the number of startups that Mr. Beecher and Mr. Sweet consider to be
20 excessive hot startups or cold startups?

21 A. The numbers Mr. Beecher noted in his rebuttal testimony he consider to be
22 excessive are hot startup numbers.

23 Q. Does a hot startup have the same expense as a cold startup?

24 A. No. Separate amounts are entered as an expense for hot and cold startups.

Surrebuttal Testimony of
Leon C. Bender

1 Q. Did the number of hot startups used by Staff's production cost model affect the
2 total expense in this case?

3 A. No. EDE did not supply to Staff any expenses for hot startups as a response to
4 Staff's data request 2910 therefore none were included in the Staff's production cost model.
5 Thus the number of hot startups had no effect upon the total expense.

6 Q. Will you address fuel price in this surrebuttal testimony?

7 A. I used fuel prices supplied by Staff witness William Harris. His testimony will
8 address this issue.

9 Q. What method is used by EDE to calculate non-contract (spot market) energy
10 prices and availability for its model?

11 A. There is no description in EDE's testimony of the method EDE used to calculate
12 the spot market energy prices and availability, nor did EDE offer an explanation at the prehearing
13 conference.

14 Q. Does EDE believe spot market energy prices and capacity are volatile?

15 A. Yes. In both Brad Beecher's and Greg Sweet's testimony they stated that spot
16 energy prices were very volatile.

17 Q. Did EDE use volatile energy prices as inputs to its production cost model?

18 A. No, the spot market energy prices used by EDE in its production cost model were
19 constant for every hour of the month.

20 Q. Did EDE use volatile spot market energy capacity as inputs to its production cost
21 model?

22 A. No. EDE used a constant spot market energy capacity of 60 MW for every hour
23 of the year except for July and August. In those months EDE did not allow their production cost
24 model to buy any spot market energy at all during the hours of 12:00 p.m. to 6:00 p.m.

Surrebuttal Testimony of
Leon C. Bender

1 Q. Are EDE's spot market prices and energy capacity reasonable?

2 A. No. Both actual spot market price and capacity available vary every hour and, for
3 most hours, vary within the hour depending upon the supplier. An example of this volatility is
4 provided from EDE's actual information supplied to the Commission in the 4CSR 240- 20.080
5 (20.080 data) data found in Schedule 1 attached hereto. This shows EDE purchased 4 MW's at
6 \$80 MWH from supplier one, 16 MW's at \$215 per MWH from supplier two and 50 MW's at
7 \$55 per MWH from supplier number five, all within the same hour. The data is too voluminous
8 to present here but for most 8,784 hours of the test year, this example holds true. Also, during
9 the hours that EDE made no energy available to its production cost model at all, as mentioned
10 above, EDE actually purchased over 15,289 MW's according to the 20.080 data. Therefore, to
11 assume prices and capacity will be constant and to not make energy available for spot market
12 purchases during peak hours as EDE does in its production cost model, is inappropriate and is
13 not supported by the actual data.

14 Q. Please discuss the alleged "irregularities" that EDE witness Gregg Sweet
15 observed in Staff's production cost model.

16 A. In Greg Sweet's testimony he gave examples of "irregularities" he found in
17 Staff's data , including the following:

18 1. "The highest price found in Staff's input production cost model is \$139.97/MWH".
19 Greg Sweet's rebuttal testimony, page 5, line 13.

20 This is incorrect. Staff provided \$200.63 /MWH on May 31, 2000 at 6:00 p.m. as a spot
21 market input price. I have explained Staff's method of calculating input spot market prices in
22 direct testimony. A comparison of actual spot prices and Staff's input price to the production
23 cost model can be found in Schedule 2 attached hereto. An explanation of this curve is provided
24 latter in this testimony.

Surrebuttal Testimony of
Leon C. Bender

1 I have noted above the volatility of spot market prices within even one hour. Because of
2 the number of purchases made in one hour, each at a different price, Staff calculates a weighted
3 average of the purchases for that hour. If I input instantaneous prices into the production cost
4 model, the production cost model would choose only to buy the low priced energy and ignore
5 the high priced energy unless absolutely necessary to meet load. Therefore, even if the actual
6 instantaneous market price is higher than the input price for a given hour, the total cost is
7 accounted for by Staff, by Staff using a weighted average price. Comparisons of highest price
8 paid, as done in Gregg Sweet's testimony, are not meaningful unless they are coupled with the
9 amount of energy bought at that price.

10 2. "There are numerous occurrences of hourly prices increasing \$30 or more for one or
11 two hours and then decreasing by the same amount." Greg Sweet's rebuttal testimony, page 5,
12 line 22.

13 Although Staff's input spot market prices vary hour-to hour, they vary no more than \$25
14 hour-to-hour only 4.2% of the time. The spot market is volatile as pointed out earlier, unlike
15 EDE, Staff's input spot market prices reflect that volatility. Numerous examples can be pointed
16 out in the actual 20.80 data that show this is. Therefore, to say that this is a problem with the
17 input is not correct.

18 3. "In July, air conditioning drives our system demands and Empire typically reaches
19 peak load at 4 to 5 p.m. Spot Market energy prices tend to peak during those afternoons hour,
20 not at night when the load is declining." Greg Sweet's rebuttal testimony, page 6, line 3.

21 Actual 20.080 data show that the maximum price paid for spot market energy during July
22 at 9:00 p.m. was \$101/MWH, which is higher than all but one price paid between 4:00 p.m. and
23 5:00 p.m. in the afternoon on all days in July. The weighted average of actual spot market
24 energy price at 9:00 p.m. was \$77.27/MWH, which is higher than the weighted average of

Surrebuttal Testimony of
Leon C. Bender

1 \$72.76 /MWH for the hours of 4:00 p.m. to 5:00 p.m. in the afternoon. Therefore, Staff's input
2 spot market energy prices reflect the higher actual prices paid at 9:00 p.m. rather than at
3 4:00 p.m. or 5:00 p.m.

4 4. "Again from Empire's experience, spot market energy in that quantity is not likely to
5 be available during a normal summer afternoon" Greg Sweet's rebuttal testimony, page 6, line 7.

6 As stated earlier in this surrebuttal testimony actual 20.080 data show that EDE actually
7 purchased 15,289 MW of spot market energy during the hours of 12:00 p.m. and 6:00 p.m. in
8 the months of July and August. For example, the actual 20.080 data also shows that EDE
9 actually purchased 305 MW at 4:00 p.m. on and 400 MW at 9:00 p.m. on August 22d of the test
10 year. If EDE actually purchased this energy, then Staff concludes it must have been available.
11 This amount was available in Staff's production cost model for only six hours but not
12 consecutively. The average amount available in staff's production cost model is much lower, as
13 shown by actual data

14 5. "Even if Empire could purchase energy in the spot market in the quantities and at
15 the prices that Staff has assumed, there is no guarantee that we could get it delivered to our
16 system." Greg Sweet's rebuttal testimony, page 6, line 14.

17 The amount of energy made available to Staff's model to purchase was less than that
18 actually purchased by EDE in three of the last five years. The fact that EDE actually did make
19 these purchases indicates the energy was available and delivered. When asked to supply data on
20 the number of hours that EDE could not purchase energy because it was unavailable or
21 undeliverable, EDE could not do so. When the SLCC is placed in service EDE will have an
22 additional 300 MW of capacity, which will make it less likely that EDE will need to purchase
23 from the spot market during peak periods. This additional capacity should lessen the concerns
24 over possible future transmission constraints and availability.

Surrebuttal Testimony of
Leon C. Bender

1 Q. Have you compared the input energy prices of Staff's and EDE's production cost
2 model with the actual energy prices for the test year?

3 A. Yes. Schedule 2 is a plot of Staff's, EDE's production cost model prices input
4 and actual energy prices paid in the test year.

5 Q. What does the curve in Schedule 2 represent?

6 A. The curve is a distribution curve that shows the range of spot purchased prices
7 and the probability (relative frequency) of occurrence for each price in that range.

8 Q. Explain what this means?

9 A. Using the curves the probability for a certain spot energy price can be found. This
10 curve shows that Staff's spot energy prices are much closer to the actual test year prices than
11 those used by EDE.

12 Q. Does this conclude your surrebuttal testimony?

13 A. Yes, it does.

**BEFORE THE PUBLIC SERVICE COMMISSION
OF THE STATE OF MISSOURI**

IN THE MATTER OF THE)
APPLICATION OF THE EMPIRE)
DISTRICT ELECTRIC COMPANY FOR)
A GENERAL RATE INCREASE)

Case No. ER-2001-299

AFFIDAVIT OF LEON C. BENDER

STATE OF MISSOURI)
) ss
COUNTY OF COLE)

Leon C. Bender, of lawful age, on his oath states: that he has participated in the preparation of the foregoing written testimony in question and answer form, consisting of 10 pages of testimony to be presented in the above case, that the answers in the attached written testimony were given by him; that he has knowledge of the matters set forth in such answers; and that such matters are true to the best of his knowledge and belief.

Leon C. Bender

Subscribed and sworn to before me this 17th day of May, 2001.
