4                                   **CASE NO. ER-2010-\_\_\_\_\_**

5                                   **I.     INTRODUCTION**

6                   **Q.     Please state your name and business address.**

7                   A.     Timothy D. Finnell, Ameren Services Company (“Ameren Services”),  
8     One Ameren Plaza, 1901 Chouteau Avenue, St. Louis, Missouri.

9                   **Q.     What is your position with Ameren Services?**

10                  A.     I am a Managing Supervisor, Operations Analysis in the Corporate  
11     Planning Function of Ameren Services. Ameren Services provides corporate,  
12     administrative and technical support for Ameren Corporation and its affiliates.

13                  **Q.     Please describe your educational background and employment**  
14     **experience.**

15                  A.     I received my Bachelor of Science Degree in Industrial Engineering from  
16     the University of Missouri-Columbia in May 1973. I received my Master of Science  
17     Degree in Engineering Management from the University of Missouri-Rolla in May 1978.  
18     My duties include developing fuel budgets, reviewing and updating economic dispatch  
19     parameters for the generating units owned by Ameren Corporation subsidiaries, including  
20     Union Electric Company d/b/a AmerenUE (“AmerenUE” or “Company”), providing  
21     power plant project justification studies, and performing other special studies.

22                         I joined the Operations Analysis group in 1978 as an engineer. In that  
23     capacity, I was responsible for updating the computer code of the System Simulation  
24     Program, which was the production costing model used by Union Electric Company

1 (“UE”) at that time. I also prepared the UE fuel budget, performed economic studies for  
2 power plant projects, and prepared production cost modeling studies for UE rate cases  
3 since 1978. I was promoted to Supervising Engineer of the Operations Analysis work  
4 group in 1985. I became an Ameren Services employee in 1998, when UE and Central  
5 Illinois Public Service Company merged. My title was changed to Managing Supervisor  
6 in February 2008.

7 **II. PURPOSE AND SUMMARY OF TESTIMONY**

8 **Q. What is the purpose of your direct testimony in this proceeding?**

9 A. The purpose of my testimony is to sponsor the determination of a  
10 normalized level of net fuel costs, which was used by AmerenUE witness Gary S. Weiss  
11 in determining AmerenUE’s revenue requirement for this case. Net fuel costs consist of  
12 nuclear fuel, coal, oil, and natural gas costs associated with producing electricity from the  
13 AmerenUE generation fleet, plus the variable component of purchase power, less the  
14 energy revenues from off-system sales.<sup>1</sup>

15 **Q. Please summarize your testimony and conclusions.**

16 A. AmerenUE’s normalized net fuel costs were calculated using the  
17 PROSYM production cost model. The major inputs for the production cost model  
18 include: hourly load data, generating unit operational data, generating unit availability  
19 data, fuel costs, off-system market data, and system requirements. The normalized

---

<sup>1</sup> “Net fuel costs” as used in this testimony is slightly different than “net base fuel costs” (“NBFC”) discussed in the direct testimony of Mr. Weiss and which is contained in the Company’s fuel adjustment clause tariff. This is because NBFC also include items that are not the product of the PROSYM modeling but which are a part of total fuel and purchased power expense included in Mr. Weiss’ revenue requirement, principally as follows: fixed gas supply costs, credits against the cost of nuclear fuel from Westinghouse arising from a prior settlement of a nuclear fuel contract dispute, Day 2 energy market expenses and Day 3 ancillary service market expenses and revenues from the Midwest Independent Transmission Operator, Inc. (“MISO”), excluding administrative fees, MISO Day 2 congestion charges, MISO Day 2 revenues, and capacity sales revenues.

1 annual net fuel costs are \$515 million, which consists of fuel costs of \$764 million and  
2 variable purchase power costs of \$51 million, offset by off-system sales revenues of  
3 \$299.6 million.<sup>2</sup>

4 **III. PRODUCTION COST MODELING**

5 **Q. What is a production cost model?**

6 A. A production cost model is a computer application used to simulate an  
7 electric utility's generation system and load obligations. One of the primary uses of a  
8 production cost model is to develop production cost estimates used for planning and  
9 decision making, including the development of a normalized level of net fuel costs upon  
10 which a utility's revenue requirement can be based.

11 **Q. Is the PROSYM model used by Ameren Services a commonly used**  
12 **production cost model?**

13 A. Yes. PROSYM is a product of Ventyx. The PROSYM production cost  
14 model is widely used either directly or indirectly by utilities around the world. By  
15 indirectly I mean that the PROSYM logic is used to run numerous other products that  
16 Ventyx offers.

17 **Q. How long has Ameren Services been using PROSYM to model**  
18 **AmerenUE's system?**

19 A. Ameren Services has been using PROSYM to model AmerenUE's system  
20 since 1995.

---

<sup>2</sup> Please note that the off-system sales revenues figures used in my testimony are on a "total company" (retail and wholesale) basis for AmerenUE. The Missouri retail share of these figures is lower by approximately 5%, and is accounted for by Mr. Weiss when he applies the Missouri jurisdictional allocation factor in computing the revenue requirement and NBFC.

1           **Q.     How is PROSYM used by Ameren Services?**

2           A.     PROSYM is operated and maintained by the Operations Analysis Group.  
3     Some of the most common uses of PROSYM are: preparation of the monthly and annual  
4     fuel burn projections; support for emissions planning; evaluation of major unit overhaul  
5     schedules; evaluation of power plant projects; and support for regulatory requirements  
6     such as Federal Energy Regulatory Commission Public Utility Regulatory Policy Act  
7     ("PURPA") filings and rate cases such as this one.

8           **Q.     What are the major inputs to the PROSYM model run used for**  
9     **calculating a normalized level of net fuel costs?**

10          A.     The major inputs include: normalized hourly loads, unit availabilities, fuel  
11     prices, unit operating characteristics, hourly energy prices, and system requirements.

12          **Q.     Do different production cost models produce similar results?**

13          A.     Most models should have similar logic for optimizing generation costs and  
14     should produce similar results, all else being equal. However, some models have a  
15     higher level of accuracy because, for example, they are able to perform a more detailed  
16     optimization for systems like AmerenUE's system with a run of river plant, a stored  
17     hydroelectric plant, a pumped storage plant, and reserve requirements. The dispatch of  
18     hydroelectric and pumped storage plants is an important part of AmerenUE's generation  
19     cost optimization and requires a model that is able to optimize those types of plants.  
20     PROSYM is such a model. Our experience with PROSYM indicates that it does a  
21     superior job of simulating complex generating systems such as AmerenUE's system.

1           **Q.     Are there other key issues relating to production cost modeling?**

2           A.     Yes. Another very important issue is how well the model is calibrated to  
3     actual results. Model calibration is done by using model inputs that reflect actual (i.e. not  
4     normalized) data for a specific time period and comparing the simulated results produced  
5     by the model to the actual generation performance for that time period. Production cost  
6     model outputs that should be compared to actual data to properly calibrate the model  
7     include: unit generation totals for the period being evaluated; hourly unit loadings; unit  
8     heat rates; number of hot and cold starts; and off-system sales volumes.

9           **Q.     How well is the PROSYM model calibrated?**

10          A.     The PROSYM model is very well calibrated as demonstrated by the  
11     results of a calibration conducted under my supervision which compared actual 2008  
12     generation to model results. For example, the calibrated model results calculated the  
13     generating output from AmerenUE to be 49,515,400 megawatt-hours ("MWh"). Actual  
14     generation was 49,336,396 MWhs, thus the model result was within less than 1/2% of the  
15     actual generation. Another example of how well the model is calibrated is reflected in  
16     the predicted off-system sales produced by the model versus the actual off-system sales  
17     for the study period. Those results (10,708,800 MWh from the model versus 10,456,820  
18     MWh actual) was within 2.4% of the actual results. Based upon my experience, these  
19     results demonstrate the high level of accuracy of the model. Detailed results of the  
20     calibration are shown in Schedule TDF-E1.

21          **Q.     What must one do to achieve a high level of calibration in modeling a**  
22     **utility's generation?**

1           A.     One must look carefully at the model inputs that could affect the results.  
2     For example, if the model's result for generation output is too low compared to actual  
3     values there are several items that would need to be reviewed. These items include the  
4     analysis of whether (1) the dispatch price is too high; (2) the unit availability factor is too  
5     low; (3) the minimum load is too low; (4) the unit start-up costs are incorrect; (5) the  
6     minimum up and down times are incorrect; and (6) the off-system sales market is  
7     incorrectly modeled.

8           **Q.     What are the implications of using a less well calibrated model to**  
9     **determine revenue requirement in a rate case?**

10          A.     A poorly calibrated model will inevitably lead to an inaccurate  
11     determination of a normalized level of net fuel costs.

12                           **IV.     PRODUCTION COST MODEL INPUTS**

13          **Q.     What type of load data is required by PROSYM?**

14          A.     PROSYM utilizes monthly energy with a historic hourly load pattern. The  
15     monthly energy reflects AmerenUE kilowatt-hour ("kWh") sales and line losses.  
16     AmerenUE's normalized sales plus line loss values were provided to me by AmerenUE  
17     witness Steven M. Wills.

18          **Q.     What operational data is used by PROSYM?**

19          A.     Operational data reflects the characteristics of the generating units used to  
20     supply the energy for native load customers and to make off-system sales. The major  
21     operational data includes: the unit input/output curve, which calculates the fuel input  
22     required for a given level of generator output; the generator minimum load, which is the  
23     lowest load level at which a unit normally operates; the maximum load, which is the

1 highest level at which the unit normally operates; and fuel blending. Schedule TDF-E2  
2 lists the operational data used for this case.

3 **Q. What availability data is used by PROSYM?**

4 A. The availability data are categorized as planned outages, unplanned  
5 outages and deratings. Planned outages are major unit outages that occur at scheduled  
6 intervals. The length of the scheduled outage depends on the type of work being  
7 performed. Planned outage intervals vary due to factors such as: type of unit; unplanned  
8 outage rates during the maintenance interval; and plant modifications. A normalized  
9 planned outage length was used for this case, as reflected in Schedule TDF-E3. The  
10 length of the planned outages is based on a 6-year average of actual planned outages that  
11 occurred between April 1, 2003 and March 31, 2009 with one exception. The one  
12 exception was to remove the 2005 Callaway Nuclear Plant refueling outage from the  
13 6-year average because the 2005 Callaway refueling outage included non-recurring  
14 outage work relating to the complete replacement of the steam generators at Callaway.

15 In addition to the length of the planned outage, the time period when the  
16 planned outage occurs is also important. Planned outages are typically scheduled during  
17 the spring and fall months when system loads are low. Another important factor  
18 considered in scheduling planned outages is off-system power prices. The planned  
19 outage schedule used in modeling AmerenUE's generation with the PROSYM model is  
20 shown in Schedule TDF-E4.

21 Unplanned outages are short outages when a unit is completely off-line.  
22 These outages typically last from one to seven days and occur between the planned  
23 outages. The unplanned outages occur due to operational problems that must be

1 corrected for the unit to operate properly. Several examples of unplanned outages are  
2 tube leaks, boiler and economizer cleanings, and turbine/generator repairs. The  
3 unplanned outage rate for this case is based on a 6-year average of unplanned outages  
4 that occurred between April 1, 2003 and March 31, 2009, and is reflected in Schedule  
5 TDF-E5.

6 Derating occurs when a generating unit cannot reach its maximum output  
7 due to operational problems. The magnitude of the derating varies based on the operating  
8 issues involved and can result in reduced outputs ranging from 2% to 50% of the  
9 maximum unit rating. Several examples of causes of derating include: coal mill outages,  
10 boiler feed pump outages, and exceeding opacity limits due to precipitator performance  
11 problems. The derating rate used in this case is based on a 6-year average of deratings  
12 that occurred between April 1, 2003 and March 31, 2009, and is reflected in Schedule  
13 TDF-E6.

14 **Q. How was the Taum Sauk Plant's availability modeled in PROSYM?**

15 A. In order to insulate ratepayers from the financial impact of the  
16 unavailability of the Taum Sauk Plant, AmerenUE's system was modeled assuming that  
17 Taum Sauk was in service. This lowers the normalized net fuel costs used in this case by  
18 capturing the economic benefit of the Taum Sauk Plant to AmerenUE's system. For the  
19 test year period, the annual operations of the Taum Sauk Plant resulted in a net fuel cost  
20 benefit of \$28.2 million, \$24.8 million of which was determined by the PROSYM model  
21 and \$3.4 million of which reflect capacity sales from the Taum Sauk Plant as addressed  
22 in the direct testimony of AmerenUE witness Jamie Haro.

1           **Q.     What fuel cost data was used to determine AmerenUE's revenue**  
2 **requirement?**

3           A.     AmerenUE units burn four types of fuel: nuclear fuel, coal, natural gas,  
4 and oil. The fuel costs are based on costs as of the end of the anticipated true-up period,  
5 February 28, 2010. The nuclear fuel costs are based on the average nuclear fuel cost  
6 associated with Callaway Refueling Number 17 which will have fuel on site as of  
7 December 2009. The coal costs reflect coal and transportation costs based upon coal and  
8 transportation prices that become effective as of January 1, 2010. The natural gas and oil  
9 prices are based on the average monthly prices for the period March, 2007 to  
10 February 28, 2010.<sup>3</sup>

11           **Q.     What off-system purchase and sales data was used in PROSYM?**

12           A.     Off-system purchases are power purchases from energy sellers used to  
13 meet native load requirements. The purchases can be from long-term purchase contracts  
14 or short-term economic purchases. The only long-term power purchase contract included  
15 as an off-system purchase in PROSYM in this case is the purchase of 102 megawatts  
16 ("MW") from Horizon Wind Energy LLC, Pioneer Prairie Wind Farm under a purchase  
17 power contract which begins September 1, 2009. The Arkansas Power & Light ("APL")  
18 purchase power contract of 160 megawatts ("MW"), which was in place during the test  
19 year ending March 31, 2009 was not modeled because the contract ends in August 2009.  
20 Short-term economic purchases are used to supply native load when the power prices are  
21 lower than AmerenUE's cost of generation and the generating unit operating parameters

---

<sup>3</sup> Actual price data was used for the period March 1, 2007 through April 30, 2009, while forward gas prices were used for the remaining 10 months through February 28, 2010. Actual price data for those 10 months will be utilized as part of the true-up in this case.

1 are not violated. A violation of the generating unit operating parameters would occur  
2 when all units are operating at their minimum load and cannot reduce their output any  
3 further. In that case, short-term economic purchases are not made even when they are at  
4 lower costs than the cost of operating the AmerenUE generating units. The price of  
5 short-term economic purchases is based on hourly market prices. The hourly market  
6 prices are based on the average market prices for the period March 1, 2007 through  
7 February 2010. An explanation of the use of power prices from this time period is  
8 provided in Mr. Haro's testimony. Mr. Haro utilized 27 months of actual price data and  
9 9 months of forward price data, subject to true-up later in this case. The volume of short-  
10 term economic purchases was assumed to be unlimited since AmerenUE is a participant  
11 in the Day 2 Energy Markets sponsored by the MISO.

12           The PROSYM modeling contains only spot sales. Spot sales are short-  
13 term economic off-system sales that occur when the cost of excess generation is below  
14 the market price of power. Excess generation is the generation that is not used to supply  
15 the native load customers. The market price for short-term economic sales is the same  
16 price as for short-term economic purchases, which were previously described. The  
17 volume of short-term economic sales was assumed to be unlimited again, since  
18 AmerenUE participates in the MISO's Day 2 Energy Markets. While no off-system  
19 contract sales were included in my PROSYM run, because no off-system contract sales  
20 existed at the time of the run, any off-system contract sales that exist through the true-up  
21 cutoff date will be included in the true-up.

22           **Q.     What system requirements are used in PROSYM?**

1           A.     The modeling of system requirements for regulation, spinning reserves  
2     and supplemental reserves has been eliminated due to the MISO ancillary services market  
3     ("ASM"), which began in January 2009. Eliminating the modeling of system  
4     requirements results in AmerenUE purchasing all of the ancillary services needed to  
5     serve its load from the MISO ASM and allows the generating units to operate (in the  
6     modeling) at full output. Allowing the generating units to operate at full output rather  
7     than holding some of their capacity back for regulation or spinning reserves results in a  
8     \$4.6 million reduction to net fuel costs. (Net fuel costs equal generation costs plus  
9     purchase power costs less off-system sales revenues).

10           **Q.     Are there other net fuel costs that cannot be determined by the**  
11     **PROSYM production cost model?**

12           A.     Yes. There are other costs and revenues that should be considered, such  
13     as: capacity purchase costs, capacity sales revenues, revenue sufficiency guarantee make  
14     whole payments, ancillary services costs and revenues, and the costs/revenues associated  
15     with load forecasting deviations and generation forecasting deviations. Mr. Haro has  
16     addressed all of the adjustments except for the load forecasting deviations, generation  
17     forecasting deviations and ancillary services costs (which are accounted for by Mr. Weiss  
18     in his Cost of Service Study).

19           **Q.     Please describe what you mean by load forecasting deviations and**  
20     **generation forecasting deviations.**

21           A.     Load forecasting deviations and generation forecasting deviations are  
22     related to the MISO day ahead and real time markets. The day ahead ("DA") market is  
23     based on the market participants' estimates of loads and generation levels for the

1 following day and the real time (“RT”) market is based on the market participants’ actual  
2 loads and generation levels. When there is a deviation between the day ahead values and  
3 real time values there is extra revenue or expense which is calculated by multiplying the  
4 MWh deviation times the difference between the day ahead locational marginal price  
5 (“DA-LMP”) and the real time locational marginal price (“RT-LMP”). For example, on  
6 January 2, 2008, for the hour ending 1 a.m., the day ahead forecast was 5,183 MW and  
7 the modeled real time load was 5,431 MW. Thus, the load was under-forecasted by  
8 248 MW. Also the DA-LMP was \$26.63/MWh and the RT-LMP was \$30.64/MWh,  
9 resulting in an additional cost of \$4.01/MWh for meeting the extra load. The cost impact  
10 of this load forecast deviation in that hour is \$994 (248 MW per hour x \$4.01/MWh =  
11 \$994). To determine the load forecasting deviations, this calculation is done for every  
12 hour and then the cost impacts for all the hours are summed for the period being  
13 analyzed. For the generation forecasting deviations, this calculation is done for every  
14 hour and for every generating unit except for the combustion turbine generators  
15 (“CTGs”) and then cost impacts for all the hours are summed for the period being  
16 analyzed. The CTGs have been excluded from the analysis because of the way the MISO  
17 dispatches the CTGs and because of the revenue sufficiency guarantee make whole  
18 payments addressed in Mr. Haro’s direct testimony.

19 **Q. What is the total impact of the load forecasting deviations and the**  
20 **generation forecasting deviations?**

21 A. The impact of load forecasting deviations is an additional cost of \$10.7  
22 million and the impact of generation forecast deviations is additional revenues of \$0.1

1 million, resulting in a net impact of \$10.6 million of additional costs. This \$10.6 million  
2 increases net fuel costs.

3 **Q. Does this complete your direct testimony?**

4 **A.** Yes, it does.
